Cystatin C as a marker of renal function in adult Nigerians with Hypertension and Diabetes

A. O. Tomi-Olugbodi, O. O. Oladapo, A. O. Olugbodi. 1Department of Pathology, Drexel College Of Medicine, Hahnemann University Hospital, Philadelphia, PA, 2Clinical Chemistry Department of Pathology, Laboratory Medicine, Staten Island University, NY, 3Department of Internal Medicine,Reading Hospital and Medical Center, Reading, PA

Background/Objective: Cystatin C (Cys C) has been suggested to be a better marker of the glomerular filtration rate (GFR) compared to the widely used serum creatinine. The aim of this study was to compare the accuracy of Cys C with that of serum creatinine in the assessment of GFR in patients with hypertension and diabetics.

Method: Twenty hypertensives and twenty diabetics were compared with forty age-matched healthy controls. Serum Cys C and serum creatinine were estimated in all study subjects and compared with the actual GFR as estimated by the Cockcroft and Gaul’s algorithm. The strength of significance of correlation was assessed using Pearson correlation (a p value of 0.05 was accepted as significant).

Results: The serum Cys C correlated well with serum creatinine (R = 0.757, p<0.01) and with the estimated GFR (R = -0.733 and - 0.710 respectively; p<0.01). However, in the ROC analysis, the AUC of serum cystatin C (0.727) was found to be superior to that of plasma creatinine (0.539).

Conclusions: Serum Cys C and serum creatinine were well correlated in evaluating GFR in hypertensive and diabetic patients. However, serum Cys C was more closely correlated with the GFR and may therefore be a more accurate test of renal function in hypertensive and diabetic patients.

The best markers for systemic inflammatory response syndrome (SIRS) criteria

K. Saito1, N. Nomura2, K. Ishizuka3, K. Yoshioka4, S. Yuasa5, T. Inaba1, M. Nakanishi1, N. Fujita2. 1HORIBA Ltd., Tokyo, Japan, 2Department of Infection Control and Laboratory Medicine, Kyoto Prefectural University of Medicine, Tokyo, Japan, 3Department of Medical Instrumental Research and Technology, Kyoto Prefectural University of Medicine, Tokyo, Japan

Background: The present study was undertaken to find out and compare the usefulness of C-reactive protein (CRP) and hematology parameters in patients with SIRS. Patient presenting systemic inflammatory response syndrome (SIRS) exhibit two or more of the following criteria: Temperature greater than 38°C or less than 36°C, Heart Rate greater than 90 beats/min, Respiratory rate greater than or equal to 20 breaths/min or PaCO2 less than or equal to 32 mmHg, WBC greater than or equal to 12,000/μL or less than or equal to 4,000/μL, and suspected or proven infection.

Some of these patients were also under treatment of antineoplastic drug. This type of treatment induces bone marrow suppression and therefore influences the immunity response to inflammation and infection. Therefore we examined WBC, LYMPH, NEUTROPHIL, ALY#, LIC#, PLT and CRP as biomarkers in patients with combination of SIRS and/ or antineoplastic drugs in order to evaluate if the bone marrow suppression could affect the predictive value of the different parameters and analyze which would be the most valuable.

Methods: We examined 51 patients that we classified into distinct 4 groups depending on the combination of presence or not of SIRS and Antineoplastic drug medication: 5 patients with SIRS(+) and Antineoplastic drug medication (+); 14 patients with SIRS(+) and Antineoplastic drug medication (-); 13 patients with SIRS(-) and Antineoplastic drug medication (+); 18 patients with SIRS(-) and Antineoplastic drug medication (-).The area under the receiver operator characteristic curve (AUROC) was determined with 4 groups. Whole blood patient samples were tested for WBC, LYMPH, NEUTROPHIL, ALY#, LIC#, PLT and CRP using Pentra MS CRP(HORIBA Ltd.)

Results: The AUROC value by 14 patients with SIRS(+) and Antineoplastic drug medication (+) and 18 patients with SIRS(-) and Antineoplastic drug medication (-) were 0.81 for CRP, 0.65 for PLT and 0.61 for WBC. And also the AUROC value by 5 patients with SIRS(+) and Antineoplastic drug medication (+) and 13 patients with SIRS(-) and Antineoplastic drug medication (+) were 0.82 for PLT, 0.8 for CRP and 0.77 for WBC. The AUROC of both PLT and CRP was 0.87. The AUROC of both WBC and CRP was 0.80. The ALY# and LIC# did provide useful information for evaluating that the patient had SIRS or not. The LYMPH and NEUTROPHIL almost had almost the same performance as WBC.

Conclusion: Some patients with SIRS(-) based on SIRS criteria also had inflammatory disease such as cholecystitis and otitis media. We evaluated patients with SIRS(-) by CRP. The results show, patients with SIRS(+) and CRP(<5mg/L) and including inflammatory disease such as cholecystitis and otitis media and patients with SIRS(-) and CRP(<5mg/L) without inflammatory disease. This shows that CRP is an excellent marker for SIRS criteria. Since WBC is affected by bone marrow suppression of Antineoplastic drug medication and CRP is not affected by it. The AUROC combination between CRP and PLT is better than the AUROC combination between CRP and WBC. Therefore, our conclusion is that CRP and PLT provide better results as supportive markers for SIRS criteria.

A case of Glutaric Aciduria type 1 in a Black South African girl

M. J. Turzyniecka. IALCH-NHLS and UKZN, Durban, South Africa

Background: Glutaric Aciduria type 1 is an autosomal recessive inborn error of metabolism caused by a deficiency of glutaryl-CoA enzyme A dehydrogenase (GCDH). If unreucnised it results in a severe extrapyramidal disease and mental retardation. It has been well described in North American and European Caucasian populations but only recently identified as potentially one of the commonest inherited metabolic disorders in black South Africans.

Methods and Results: We present a case of 9 month old Black South African girl who was admitted for investigations of sudden hypotonia following a fall from her mother’s back. There was no family medical history of note. She was delivered at term by normal vaginal delivery and had normal developmental milestones until the fall. She had no previous medical history. She had relative macrocephaly (head circumference 46cm - 97th centile) and was globally hypotonic with hyporeflexia. She had normal renal and liver function tests, lactate, ammonia, amino acid profile and negative reducing substances screen. She had high urine glutaric acid at 4061umol/mmol creatinine (reference <30) and 3-OH glutaric acid at 49 umol/mmol creatinine (reference < 2.5).

MRI of brain showed T2 bilateral hypointensity of the basal ganglia, cerebral peduncles and central tegmental tracts, symmetrical restricted diffusion of globus pallidus in keeping with acute on chronic changes of pre-existing Glutaric aciduria type 1.

Conclusion: Macrocephaly is an important clinical sign of many neurometabolic disorders and one of the earliest signs of Glutaric Aciduria type 1 (GA type 1) thus warrants screening in all cases of macrocephaly of unknown origin regardless of ethnicity. GA type 1 typically presents with acute cerebral injury precipitated by an intercurrent infectious illness. It is a preventable and treatable disorder requiring and central tegmental tracts, symmetrical restricted diffusion of globus pallidus in keeping with acute on chronic changes of pre-existing Glutaric aciduria type 1.

Assessment Of Serum And Urine Sialic Acid In Sickle Cell Anaemia Patients

S. E. Idogun, E. Oriseseyigbemion-Sakpa. university of Benin Teach Hospit, BENIN, Nigeria

Aim and objectives: To assess serum and urine sialic acid and compare their values with other biochemical markers of nephropathy in patients with sickle cell anaemia.

Patients and methods: It was a cross sectional descriptive study that involved adult (18 – 60 years) sickle cell anaemia patients that were clinically stable without sickle cell anaemia crisis. The control participants were healthy volunteers that were age-matched. Urine and blood specimens were obtained from the participants. The urine albumin analysis was by Lowry method, urine and plasma creatine was by Jaffé’. Kinetic method, while the serum and urine sialic acid was by standard Ehrlich (p- dimethyl amino benzaldehyde) method. Data were analysed using SPSS version 16.

Results: Sixty eight of the subjects were sickle cell anaemia patients while 30 respondents served as control. Table 1, shows the plasma and urine results of the studied analytes in the sickle cell anaemia patients and controls. There was a negative

S20 CLINICAL CHEMISTRY, Vol. 60, No. 10, Supplement, 2014
Concentration of serine peptidase was significantly different between the two groups (p = 0.001). The mean concentration of serine peptidase in the control group was 2.17 ± 0.50 mg/dL, while in the study group it was 1.50 ± 0.20 mg/dL.

Conclusions: The results of this study suggest that serine peptidase levels are lower in patients with hepatitis C than in healthy controls. This finding may have implications for the early diagnosis and management of hepatitis C.

M. C. Freire1, I. Bendel1, M. L. Moreira1, L. L. Leite1, A. J. L. Jorge1, M. G. Rosa1, E. T. Mesquita1, 1DASA, Rio de Janeiro, Brazil, 2Universidade Federal Fluminense, Niterói, Brazil

Background: The Neutrophil Gelatinase Associated Lipocalin (NGAL) is a glycoprotein involved in the processes of innate immunity and inflammation. Initially described in neutrophils and epithelial cells, it is also produced by macrophages and smooth muscle cells in atherosclerotic lesions. It activates proteolytic processes linked to metalloproteinase 9 (MMP-9), considered to be responsible for vascular remodeling and rupture of atherosclerotic plaque, leading to clinical presentations of cardiovascular diseases (CVD).

Objectives: To evaluate the associations of NGAL with parameters known as cardiovascular risk factors and criteria for metabolic syndrome.

Methods: Observational, cross-sectional study of a sample (n = 219) of outpatients assisted by the Family Medicine Program in the city of Niterói, Brazil, aged 45 years and older. All data and samples were collected between August 2011 and August 2012. NGAL serum levels were determined by sandwich ELISA (Bioporto Diagnostics), samples were frozen at -80°C until first thawed. We evaluated its associations with several risk factors.

Results: Of the parameters tested, we observed significant positive correlation between NGAL means and age, creatinine, leukocyte count, Framingham estimated risk, and a negative correlation with HDL cholesterol (Table 1).

Discussion: To establish preventive strategies for CVD is one important goal of health systems, and it depends on accurate individual risk assessment. There are consistent data from studies in animals and humans that support the importance of NGAL in the patho-physiology of atherosclerosis and CVD. The biological effect of NGAL in atherosclerosis is suggested by the co-localization of NGAL and MMP-9 expression in human carotid atherosclerotic plaques with increased gelatinase activity in these tissues. The quest for understanding the role of this new biomarker in predicting cardiovascular events is of paramount importance, and at this point of the study we could show its association with HDL and to Framingham risk estimates.

A study of the parasitic causes of anaemia in children under five(5) years of age in the Bolgatanga municipality, Ghana

C. NKRUMAH1, S. ALHASSAN ANEYIRE1, 1METHODIST HOSPITAL, WENCHI, Ghana, 2COLLEGE OF HEALTH, KINTAMPO, Ghana

Background: Anemia is a condition affecting children especially those less than 5 years, and pregnant women in the world (WHO, 2000). In tropical and developing countries, anemia is particularly prevalent with 50% or more of pre-school children and pregnant women being moderately or severely anemic (Chesbrough, 2006). It is against this background that this research is being conducted.

Methods: This study represents the results of a descriptive cross-sectional study to establish the prevalence, magnitude and causes of anemia among children less than 5 years of age and pregnant women in the Bolgatanga municipality, Ghana.
5 years in the Bolgatanga municipality. Simple random sampling technique was used to obtain specimen from 100 participants following informed consent. Specimens analyzed included stool (wet preparation with physiological saline) for intestinal parasites and blood samples for hemoglobin measurement and detection of the presence of malaria parasites using Rapid Diagnostic Technique (RDT) kits. Actual measurement of their hemoglobin (Hb) was done using a Sysmex analyzer. Anemia was defined as haemoglobin concentration less than 11.0 g/dl (Cheesbrough, 2006).

**Results:** The prevalence of anemia among the children was 62%. Of the anemic children, 35 (56%) showed presence of malaria parasites in their bloodstream whiles 18 (29%) had intestinal parasites. 42(66%) of the anemic children had Hb between 10.0 and 11.0 g/dl (mildly anemic), 13.0 (23%) had Hb between 7.0 and 9.9 g/dl (moderately anemic), with 7 (11%) of them being severely anemic (Hb below 7 g/dl). All the parasites detected in the stool samples were hookworm. The presence of these intestinal parasites and malaria parasites in the stool and blood respectively had a significant association with low Hb (p<0.005).

**Conclusion:** Based on the results of the study, the prevalence of anemia was high in the study population. Malaria parasitaemia was a major cause of anemia in our environment followed by hookworm infestation. The study recommends among other things that the Ministry of Health should embark on intensive health education programs in the communities on early detection of malaria and hookworm infestation and enforce their prevention.

**Fecal Biomarker Testing Identifies Exocrine Pancreatic Insufficiency in Patients with Possible Irritable Bowel Syndrome**

Objective: 1) To use fecal biomarker testing to identify a subset of patients with symptoms of irritable bowel syndrome (IBS) that might be explained by the presence of exocrine pancreatic insufficiency (EPI), and 2) to identify within that subgroup additional fecal biomarkers that might suggest a primary disease process capable of causing secondary EPI.

Relevance: IBS, long considered a “diagnosis of exclusion,” is now recognized as an “umbrella diagnosis,” identifying a heterogeneous group of patients who may in fact have one or more of several underlying, treatable diagnoses. EPI is one such diagnosis, but few studies have examined its prevalence or biological context in the setting of possible IBS. Because EPI may occur secondary to another gastrointestinal problem such as inflammation or parasitic infection, fecal biomarkers suggesting such processes may further clarify the diagnostic picture in patients presenting with symptoms consistent with IBS. A fecal biomarker panel with appropriate components may thus represent an important role for clinical laboratory medicine in diagnosis and management of conditions producing symptoms consistent with IBS.

Methods: One-year analysis of de-identified stool testing data for fecal pancreatic elastase-1 (FPE1) in all patients for whom stool specimens were submitted for testing bearing at least one of 13 ICD-9 codes indicating the potential for IBS. FPE1 testing was conducted using a standard dual monoclonal antibody ELISA technique with binding sites for two unique epitopes on the human PE-1 molecule. When biomarker data on other conditions were available on the same specimen, they were analyzed for significance.

**Results:** Thirty-three percent of patients with symptoms of IBS were found to have one or more of several underlying, treatable diagnoses. EPI is one such diagnosis, and 9% of patients with symptoms of IBS were found to have exocrine pancreatic insufficiency. Fecal elastase-1 (FPE1) testing in all patients for whom stool specimens were submitted for testing revealed that 858 (9.4%) of all records, and 13 IBS-related ICD-9 codes and also a result of FPE1 testing in the range 200-199 was fecal calprotectin and EPX, as well as with evidence of infection with Blastocystis hominis, non-Blastocystis parasites, H. pylori, and entamoeba. FPE1 of 100-199 was significantly associated with parasitic infection as well. Conclusions: Among patients in whom IBS was a consideration, fecal biomarker testing revealed that 9.4% had indications of some degree of exocrine pancreatic insufficiency by FPE1. Fecal biomarker testing was also more likely to suggest presence of an inflammatory or parasitic gastrointestinal condition in patients with abnormal FPE1, suggesting that in some cases EPI itself might be secondary to such underlying processes, and indicating potential lines for further evaluation of possibly treatable diagnoses. Further prospective studies with definitive patient follow-up are recommended.

**Association between the Delta Estimated Glomerular Filtration Rate and the Prevalence of Monoclonal Gammapathy of Undetermined Significance in Korean Males**

T. Jeong, W. Lee, S. Chun, W. Min. University of Ulsan College of Medicine and Asan Medical Center, Seoul, Korea, Republic of

**Background:** The prevalence of monoclonal gammapathy of undetermined significance (MGUS) varies with age, gender, and ethnicity. We investigated the association between the reduction in the estimated glomerular filtration rate (eGFR) and the prevalence of MGUS in healthy Korean males.

**Methods:** We enrolled 723 healthy Korean males who visited the hospital for regular health checkups. Serum creatinine concentration, serum electrophoresis, serum immunofixation, and the serum free light chain assay were performed. Data, including age, date of health checkup, and previous serum creatinine concentrations were obtained from electronic medical records. We calculated the delta eGFR per year and the prevalence of MGUS was compared based on the delta eGFR per year.

**Results:** Thirteen (1.8%) of seven hundred and twenty-three participants exhibited the monoclonal band on serum immunofixation. Prevalence of MGUS by age group was 0.00% (0/172 for 40s), 1.63% (6/367 for 60s), and 3.80% (7/184 for >60 years). The median decrease in delta eGFR per year was 5.3%. The prevalence of MGUS in participants in their 50s with >5.3% decline in delta eGFR per year was significantly higher than those with <5.3% decrease in delta eGFR per year (3.16% vs. 0.00%; p = 0.049). The prevalence of MGUS in participants in their 50s with >5.3% decrease in delta eGFR per year was similar to that of healthy males in their 60s.

**Conclusion:** Using the rate of reduction in delta eGFR per year in healthy Korean males who had their serum creatinine level checked regularly may increase the MGUS detection rate in clinical practice.

**An Update on a Candidate BK Virus DNA Standard Reference Material**

J. Harenza1, L. Cook2, P. M. Vallone3, 1NIST, Gaithersburg, MD, 2University of Washington, Seattle, WA

**Background:** The polyomavirus, BKV, is widespread in the population due to primary infection during childhood and largely remains latent in the majority of individuals. However, illnesses as a result of BKV occur in immunocompromised patients, organ transplant, HIV/AIDS-infected, or diabetic patients. Two common illnesses resulting from BKV, hemorrhagic cystitis and nephropathy, occur in transplant patients, as prescribed anti-rejection medications can weaken the immune system. This often leads to renal allograft failure. To treat BKV, accurate quantitation of viral load is necessary for proper adjustment of anti-rejection medications in an effort to improve an individual’s immune function. However, current BKV standards are only available for the Ia genotype of the virus, and it has been well-documented that using assays specific to Ia can lead to underestimation of viral load of other genotypes, due to primer and/or probe binding site polymorphisms. Therefore, we propose a candidate reference material panel of BKV genotypes to aid in precise measurements of viral load.

**Methods:** Viral DNA was extracted from six available clinical isolates and distinct genotypes (Ia, Ic, III, IV, V, VI) of the BK virus. Single site restriction digestion was performed to linearize each viral genome and long-range PCR was performed to amplify entire genomes. Each amplicon was ligated into a plasmid backbone, transformed into, and subsequently propagated in, XL-10 Gold E. coli cells. DNA was extracted, purified, and re-linearized to enable sequencing and accurate copy number measurement. Using the Illumina MiSeq platform, whole genome sequencing was performed for each genotype. New primer and probe sets, specific to each genotype, were designed using this sequence information and optimized for quantitative PCR (qPCR) and digital PCR (dPCR).

**Results and Future Goals:** We have amplified and sequenced six full-length BKV genomes. Next-generation sequencing information allowed us to design and optimize efficient (between 90-110%) primer and probe sets for both qPCR and dPCR platforms. Homogeneity and stability studies will be performed for each DNA construct using the newly developed assays, and the materials will be certified for genome copy number using dPCR.

**Conclusion:** The availability of a panel of BKV DNA genotypes as potential reference materials will enable traceability for manufacturers of calibrator materials. This will ultimately improve upon the consistency and accuracy of viral load quantitation measurements across laboratories, leading to improved dosing regimens in infected patients.

**CLINICAL CHEMISTRY, Vol. 60, No. 10, Supplement, 2014**
Can Procalcitonin or Lactate help with Sepsis Evaluation in Cancer Patients?

D. R. Mendu, M. Fleisher, S. L. McCash, Q. Xiang, L. Miller, M. S. Pessin, L. V. Ramanathan. Memorial Sloan-Kettering Cancer Center, New York, NY

Objective: Severity of illness due to sepsis in patients with cancer is a major clinical complication and contributes to high mortality in this patient population. We evaluated two biomarkers used to help discriminate between bacterial infection and non-infectious acute-phase reactions: lactate (LA) and procalcitonin (PCT).

Methods: A cohort of 40 random patients with malignant disease admitted to Memorial Sloan Kettering Cancer Center was studied. Out of these 40 patients, 10 were considered as “controls” using the sepsis diagnostic criteria of lactate < 2.0 mmol/L, and negative bacterial cultures: and PCT< 0.5 ng/mL per manufacturer’s recommendations. Six out of the forty patients had viral infections. LA and PCT were measured at the time of admission followed by an additional sample collection for each patient within 24 hours. Heparinized blood samples were obtained and the plasma used for LA analysis on the Nova pHOX and for PCT determined by an Enzyme Linked Fluorescent Antibody analysis on the mini Vidas (BioMérieux S. France). Concordance studies between LA and PCT were done.

Results: Our study demonstrated that elevated LA and PCT levels have only a 50% concordance. PCT was elevated in 50% of the patients and demonstrated a lack of concordance with plasma Lactate. Additionally, we observed that the PCT was elevated in patients who were negative for bacterial infection, based on microbiological cultures, and did not correlate well with LA concentrations > 4 mmol/L. The six patients with viral infection had significantly elevated PCT levels and the LA levels were < 4 mmol/L. In order to examine the possible effect of pre-analytical factors that may explain the LA/PCT discordance, we analyzed LA stability in five healthy volunteers at different time points at room temperature. Within 15 minutes, the LA in heparinized blood increased steadily, and by 30 minutes, LA concentrations were almost 40% higher than the initial LA measurements. Conclusions: Our preliminary findings suggest that PCT levels were consistently high in cancer patients without sepsis. Our data also indicates a poor correlation between LA and PCT in cancer patients evaluated for suspected bacterial infection and neutropenia. Increased LA concentrations could be due to pre-analytical variation, oxygen deficiency due to mitochondrial oxidative phosphorylation, inhibition by interleukins (ILs), tumor necrosis factor (TNF) or a combination of the latter. These data support the already known poor specificity of LA as an accurate indicator of sepsis. Further clinical investigation is also needed to explain elevations in PCT in the absence of bacterial infection in patients with cancer.

Based on these data, the significance of PCT in cancer patients without infection is unclear and requires further investigation. Our data also suggests a need to investigate the relationship between plasma LA and PCT in the clinical evaluation of sepsis in cancer patients.

Urinalysis/Microscopy Reflex to Urine Culture on iRICE L.® Complete Urinalysis™ Workcells: Are We There Yet?

Background: Urinary Tract Infection (UTI) is serious health problem, it is very common among the geriatric population, it is the second most common type of infection (second only to respiratory tract infection), and can cause serious complications and it is a significant cause of morbidity and death, with the expected death rate as high as 3% in those who develop pyelonephritis. The high mortality rate is largely due to delayed presentation and the development of bacteremia/sepsis.

Urinalysis (UA) is one of the most frequently requested tests; it is estimated that between 200 and 300 million UA are performed yearly in the United States. It is an invaluable tool in the diagnosis of UTI, malignancy, calculi, and detecting systemic diseases affecting the kidneys.

Methodology: 1,634 specimens were collected for urinalysis and culture from residents in Long-Term Care Facilities over a period of 2 weeks. Urinalysis and microscopy was done using iRICE L.® automated system. All the specimens were cultured; the culture was done using MicroScan Walkaway 96/160 conventional panels. We used urine culture as the reference standard, no growth or <10,000 colony-forming unit/ml were considered negative, cultures with > 50,000 colonies colony-forming unit/ml were considered positive. The urine instrument generates a “urine culture candidate report” when at least one of the five bacteriuria parameter (Nitrite, Leucocyte Estrase, and microscopy values: white blood cells, bacteria and all small particles); the report was used to assess its effectiveness for urine culture screening.

Results: 801 (49.0%) had positive culture. 1344 (82.3%) specimens were identified as urine culture candidates. Of the 1,344 that were identified as candidates, 772 (57.4%) had positive culture, 547 (40.7%) were negative, 25 (1.9%) were contaminated. 290 (17.7%) specimens were not selected as culture candidates because of the negative urinalysis; of these specimens 29 (10%) had positive culture and 259 (89.3%) were negative.

Conclusion: using the candidate for urine culture would have avoided urine culture on about 15% of the patients but would have missed the diagnosis for 10% of the patients that were considered as having normal specimens. Urinalysis and microscopy still lack the sensitivity and specificity to be used alone to diagnose urinary tract infection, more work needed to establish better parameters and algorithm to be used when screening patients for UTI using urinalysis.

Fatigue in rheumatoid arthritis and its relation to interleukin-6 serum level

d. I. hashad, A. Helal, E. Shahine, M. Hassan, R. Abdel Moneim. FACULTY OF MEDICINE, alexandria, Egypt

Objectives: This work aimed to investigate the occurrence and level of fatigue and its relation to IL-6 serum level in rheumatoid arthritis (RA) patients. Patients and methods: The study included 60 patients with RA diagnosed according to the 2010 ACR-EULAR classification criteria for RA and 30 healthy controls. Patients were included if they were above 18 years and fulfilled a score P6 over 10 of the ACR-EULAR classification criteria for RA. Disease activity was assessed using 28 joint disease activity score (DAS28), erythrocytes sedimentation rate (ESR) and C-reactive protein (CRP). Fatigue was assessed using the Bristol Rheumatoid Arthritis Fatigue Multidimensional Questionnaire (BRAF-MDQ) and serum IL-6 level was measured in patients and controls using enzyme-linked immunosorbent assay (ELISA) technique. Results: The BRAF-MDQ was significantly higher among patients (mean ±50.6 ± 15.2) than controls (mean ± 7.81 ± 3.7) (p= 0.001). Patients mean IL-6 serum level was 35.05 ±2.23 pg/ml and 4.72 ±3.09 pg/ml among control subjects (p= 0.001). DAS 28 ranged between 4.35 and 7.67. Mean 1st hour ESR was...
A Novel Missense Mutation in the Androgen Receptor Gene Causes the Complete Androgen Insensitivity Syndrome

X. Liu¹, Z. Cai², L. Xie³, L. Ji¹. 1Peking University Shenzhen Hospital, Shenzhen, China, 2Hengyang Blood Center, Hengyang, China, 3Shenzhen Research Institute of Population and Family Planning, Shenzhen, China

A 22-year-old, phenotypically female individual was presented at hospital because of primary amenorrhea. The physical examination revealed normal female external genitalia, sparse pubic hair and developed breasts with juvenile nipples and pale areolas. A mass was found in the left inguinal canal. The gynecological examination revealed a short, blind-ending vagina 7.0 cm in length. Ultrasonography of the pelvis showed no uterus, fallopian tube, or ovaries. The hormonal profile were as follows: follicle-stimulating hormone (FSH) 23.4 IU/L, luteinizing hormone (LH) 39.6 IU/L, testosterone (T) 23.0 nmol/L, estradiol (E₂) 177 nmol/L. FSH and LH were above the upper normal limit. T was elevated compared with the normal female level and was in the normal range for males. E₂ was in the normal range for females. Cytogenetic analysis from the peripheral blood lymphocytes revealed a 46,XY karyotype in the patient.

DNA (genomic DNA was extracted from peripheral blood of the patient) sequencing of polymerase chain reaction (PCR) products revealed a single-nucleotide substitution (A→T) at position 2184 in exon 3, resulting in the conversion of arginine (AGG) to tryptophan (TGG) at amino acid position 608 in the DNA-binding domain of the AR (Figure 1). The novel missense mutation of exon 3 in the AR gene, resulting in the nonfunctional protein, is responsible for the clinical symptoms of CAIS.
Tuesday, July 29, 9:30 am – 5:00 pm

**Clinical Studies/Outcomes**

**Objective:** The Elecsys® Periostin assay is being developed as a companion diagnostic for the anti-IL13 drug lebrikizumab in asthma. The current clinical trial assay was used to evaluate the precision performance according to CLSI EP 5-A2 under field conditions. The assay was used in the Phase Ib lebrikizumab trials (LUTE and VERSE) to stratify asthma patients by baseline serum periostin levels.

**Methods:** The Periostin assay is an automated electrochemiluminescence immunoassay. The assay requires a total of 18 minutes to perform. It employs two monoclonal antibodies targeted to Periostin via the sandwich principle. The assay is used for the in vitro, quantitative determination of Periostin in human serum.

**Imprecision testing was conducted using a total of eight human serum pools covering the entire measuring range (10-160 ng/mL). This experiment was carried out at three external routine laboratories, on threecobas e 601 analyzers. The experimental setting included two replicates in two runs per day for twenty-one days (EP-5), using two reagent lots. Using this design, repeatability, intermediate precision and reproducibility were estimated based on a variance-components model.

It has been shown that high serum Periostin levels (≥ 50 ng/mL) are associated with benefit from lebrikizumab in asthma (Phase II lebrikizumab trial MILLY; Corren et al. NEJM, 2011). LUTE and VERSE were randomized, multicenter, double-blind, placebo-controlled, parallel-group clinical trials. Patients were aged 18 years and older whose asthma remained uncontrolled despite daily treatment with inhaled corticosteroids (ICS) therapy and a second controller medication. Patients were randomized in a 1:1:1:1 ratio to receive subcutaneous lebrikizumab at 250 mg, 125 mg or 37.5 mg every 4 weeks or placebo, administered every 4 weeks. The primary endpoint was reduction in exacerbation rate and the main secondary endpoint was percent change in forced expiratory volume (FEV1). Efﬁcacy analysis for each endpoint was assessed in subgroups of periostin high (≥ 50 ng/mL) and low (<50 ng/mL) patients.

**Results:** Repeatability for the Periostin assay varied from 1.24% to 1.64% CV, intermediate precision varied from 2.30% to 2.56% CV and overall reproducibility varied from 3.10% to 3.95% CV. The precision obtained fulﬁlled the assay speciﬁcation and met the requisite target to segment subjects properly to the correct periostin stratum.

A total of 463 patients were enrolled in both studies, of which 42% of patients were classiﬁed as periostin-high. Compared with placebo, the exacerbation rate was reduced by 60% (95% CI: 18, 80) in periostin-high patients (combined dose levels) and by 5% (95% CI: -81, 47) in periostin-low patients. FEV1 at 12 weeks increased in the periostin-high group by 9.1% (95% CI: 2.2, 15.9) over placebo, compared with a 2.6% (95% CI: -2.7, 7.9) increase over placebo in the periostin-low group.

**Conclusion:** The Periostin assay demonstrated good precision and was used for clinical sample testing to stratify patients in the lebrikizumab Phase II trials. Lebrikizumab treatment reduced the exacerbation rate and increased FEV1 in patients with uncontrolled asthma on ICS and a second controller, particularly in those who were periostin-high, conﬁrming the ﬁndings from the Phase II trial MILLY.

**SDMA Outperforms Serum Creatinine-Based Equations in Estimating Kidney Function Compared with Measured GFR**

D. A. Payto, J. M. El-Khoury, D. R. Bunch, S. Wang. Cleveland Clinic, Cleveland, OH

**Background:** Symmetric dimethylarginine (SDMA), a catabolic product of post-translational modiﬁed arginine containing proteins, is an emerging biomarker for renal function. Recent studies have shown that there is a correlation between SDMA and renal function in chronic kidney disease (CKD) patients. However, there are no published reports that have investigated the performance of SDMA versus creatinine in estimating glomerular ﬁltration rate (GFR) in both CKD and non CKD patients. The objective of this study was to determine the correlations of measured GFR with SDMA levels, creatinine levels, eGFR (MDRD), and eGFR (CKD-EPI). Method: EDTA plasma samples were obtained from 21 male and 19 female adult subjects who were 21-76 years old. These subjects had GFR measured by radioactive inulin intravenous clearance, ranging from 13-151 mL/min/1.73’². Arginine, asymmetric dimethylarginine (ADMA), and SDMA in EDTA plasma were assayed using a previously validated LC-MS/MS method. Results: A power regression analysis showed R²=0.7544 and R²=0.5827 the correlation of measured GFR with SDMA and creatinine, respectively. A linear regression analysis was used for the correlation of measured GFR with eGFR by MDRD and eGFR by CKD-EPI with R²=0.6534 and R²=0.7183, respectively.

**Conclusion:** Correlation of measured GFR with SDMA was higher than those with creatinine, eGFR (MDRD), and eGFR (CKD-EPI) in a population of CKD and non CKD patients. In Conclusion: SDMA outperforms creatinine and creatinine-based equations in estimating kidney function compared with measured GFR.

**A-103**

**Equivalence between high sensitivity CRP and low sensitivity CRP tests in infants**

S. N. Narla, P. Nelson, D. Brass, B. Horne, Y. Zhu. Medical University of South Carolina, Charleston, SC

**Background:** C-reactive protein (CRP) is an acute-phase protein that rises in response to inflammatory processes. Most clinical laboratories perform two different assays for measuring CRP, low sensitivity CRP (ls-CRP) and high sensitivity CRP (hs-CRP). The hs-CRP is usually used in combination with other biomarkers to assess risk of developing myocardial infarction in patients presenting with acute coronary syndromes and risk of cardiovascular disease in adults who do not manifest disease at present. Along with the monitoring of inflammatory process, ls-CRP is also used in the diagnostic evaluation of sepsis in neonates and infants. CRP values in healthy infants and neonates vary from a range of 0.2 mg/dL to 1.0 mg/dL. Therefore, for the diagnosis of sepsis, a concentration >1.0 mg/dL is considered abnormal and serial testing is frequently performed. The objective of this study is to verify whether the hs-CRP method is equivalent to ls-CRP in monitoring inflammatory processes in infants.

**Methods:** For this study, 33 serum samples with hs-CRP higher than 0.7 mg/mL from a patient population of <1 year old were collected. These serum samples were analyzed by both hs-CRP and ls-CRP assays on the UniCel Dxc800 Systems by turbidimetric immunoassays. In both methods, CRP reacts with a specific antibody to form insoluble antigen-antibody complexes. The turbidity was measured at 340 nm for ls-CRP with an analytical measurement range of 0.7mg/dL to 20 mg/dL and at 940 nm for hs-CRP with the range of 0.02 mg/dL to 6 mg/dL. Equivalence of these two methods for the chosen population was evaluated with an allowable total error of 0.6 mg/dL or 25%, whichever is higher. Also, 18 samples with ls-CRP values <0.7 mg/dL were analyzed by both methods.

**Results:** 33 specimens were compared over a range of 0.22 to 23.35 mg/dL by ls-CRP. The difference between the two methods was within the allowable error for 31 of 33 (94 %) specimens, with a linear regression equation y=0.886x+0.3713 and the correlation coefficient (R) of 0.9908. The error index was determined by the ratio of the difference between two methods (hs-CRP – ls-CRP) to the allowable total error and the average error index was -0.13 with a range of -1.03 to 1.25. For 12 samples with concentrations < 2.4mg/dL by ls-CRP, the mean bias was -0.16 mg/dL with a standard deviation of 0.39 mg/dL, out of which 2 samples had error >0.6 mg/dL. For 21 samples with concentrations > 2.4mg/dL by ls-CRP the mean bias was -1% with a standard deviation of 12%. Also, all the 18 samples with CRP concentrations <0.7mg/dL by ls-CRP presented values <0.7 mg/dL by hs-CRP method.

**Conclusions:** CRP concentrations in the patient population of <1 year old infants can be analyzed by both Beckman Coulter UniCel Dxc ls-CRP and hs-CRP methods to monitor inflammatory processes. Overall, the hs-CRP assay is equivalent to the ls-CRP method for the majority of patients (94%). However, in about 17% patients with CRP < 2.4 mg/dL, the bias may be greater than the allowable total error.
Prevalence of Metabolic Syndrome and its Components according to Different Definitions among Nepalese Type 2 Diabetic Patients

D. R. Pokharel¹, D. Khadka², M. Sigdel¹, N. K. Yadav¹, L. B. Sapkota¹, P. Rayamañhi¹, S. K. Jha¹, A. Yadav¹, P. S. Shukla¹, ¹Manipal College of Medical Sciences and Teaching Hospital, Pokhara, Nepal, ²Gandaki Medical College and Teaching Hospital, Pokhara, Nepal

Objective: The objective of this study is to determine the prevalence of the metabolic syndrome (MetS) and its components according to WHO (1998), NCEP ATP III (2005), IDF (2005) and newly introduced Harmonized (2009) criteria and determine their agreement and disparity in diagnosing MetS among Nepalese patients with type 2 diabetes mellitus (DM).

Methods: Patients with type 2 DM without any other acute or chronic illness were recruited for the study from the Manipal Teaching Hospital (MTH), Pokhara, Nepal. Clinical data were obtained by interviewing the patients with structured questionnaire, anthropometric and blood pressure measurements and biochemical analyses of the blood samples. The analyzed biochemical parameters included fasting serum glucose, insulin, homeostasis model assessment of insulin resistance (HOMA-IR), triglycerides and high density lipoprotein cholesterol. Statistical analysis included usage of Student’s t and Chi square tests, kappa statistics and 95% confidence intervals.

Results: 1061 (male: 589, female: 472) type 2 diabetic patients aged between 30-89 years were included in the study. The total age adjusted prevalence was 69.9 %, 73.9%, 66.8% and 80.3% according to WHO, NCEP ATP III, IDF and Harmonized definitions, respectively. The Harmonized definition outperformed other definitions in diagnosing MetS. Prevalence generally increased with the age and remained highest in the age range of 50-69 years in both the sexes. It was significantly higher in females (p=0.000) according to WHO, NCEP ATP III and Harmonized definitions. Patients of Dalit community had the highest prevalence according to NCEP ATP III (p=0.033) and Harmonized (p=0.037) definitions whereas patients of Mongol and Newar communities outnumbered other communities according to WHO (p=0.001) and IDF (p=0.037) definitions, respectively. The overall agreement was substantial between Harmonized and NCEP ATP III (κ=0.62), moderate between Harmonized & IDF (κ=0.54) and NCEP ATP III & WHO (κ=0.51), fair between NCEP ATP III & IDF (κ=0.33) and Harmonized & WHO (κ=0.37) and slight for WHO & IDF definitions (κ=0.26). The most frequent component of MetS was central obesity according to the WHO (98.8%), IDF (99.9%) and Harmonized (85.6%) definitions respectively. However, decreased HDL was the most frequent component (93.5%) according to NCEP ATP III definition. On the other hand, hypertension was the least frequent component according to all four definitions (WHO: 66.2%, NCEP ATP III: 72.1%, IDF: 65% & Harmonized: 67%). The overall diagnostic potential of the NCEP ATP III definition was the best among others [sensitivity: 90.8%, specificity: 98.9%, positive predictive value: 99.9% and negative predictive value: 49.9%] while comparing with Harmonized definition as the gold standard.

Conclusion: The prevalence of MetS in type 2 DM is very high in both genders irrespective of the definitions used and increases with age thus posing a potential threat of increased cardiovascular diseases in this group of patients. The patient education and control of the modifiable risk factors for MetS should be given due priority by the clinicians in the management of subjects with type 2 DM.
CEDIA® Cyclosporine Applications for the Beckman Coulter AU480, AU680 and AU5800 Analyzers

D. L. Cheng, T. Miwa, C. Wong. Thermo Fisher Scientific, Fremont, CA

Background: Cyclosporine is an immunosuppressant used in the treatment of autoimmune diseases and the reduction of tissue rejection following organ transplantsations. Although its mechanism of action is still under investigation, cyclosporine appears to affect the metabolism of T-helper lymphocytes and T-suppressor lymphocytes, resulting in the inhibition of the immune system. Although cyclosporine is safely used over an established narrow range of concentrations, inadequate dosing may lead to organ rejection, while overdose may lead to a number of adverse effects including nephrotoxicity, and hepatotoxicity. The probability of adverse effects on users' health increases with drug concentration. Therefore, it is crucial to monitor cyclosporine levels to achieve optimal immunosuppressive effects in patients.

Methods: The CEDIA Cyclosporine PLUS Assay is based on the enzyme β-galactosidase, which has been genetically engineered into two inactive fragments. Cyclosporine in the human whole blood sample competes with cyclosporine conjugated to one inactive fragment for antibody binding site. Once cyclosporine in the sample binds to antibody, inactive enzyme fragments reassociate to form active enzymes. The amount of active enzyme results in an absorbance change that is directly proportional to the amount of cyclosporine in the sample, and is measured spectrophotometrically. The Beckman Coulter AU480/AU680/AU5800 analyzers are new applications for the CEDIA Cyclosporine PLUS Assay. Performance measures of the CEDIA Cyclosporine PLUS Assay on the Beckman Coulter AU480/AU680/AU5800 analyzers were conducted in low-range (25-450 ng/mL) and high-range (450-2000 ng/mL) assay studies. Analyzer performance was determined for precision, linearity, limit of detection, and accuracy. Correlation studies using the AU480/AU680/AU5800 analyzers were conducted against the reference analyzer, Hitachi 911.

Results: All studies were evaluated using CLSI guidelines. Five levels of cyclosporine concentration were used in the studies. The precision ranged from 7.1 to 3.1%CV for within-run and 12.7 to 8.6%CV for total run. Low range linearity was measured and confirmed over a range of 9.08-427.85 ng/mL on the AU480/AU680/AU5800. High range linearity was measured and confirmed over a range of 590.1-2027.6 ng/mL on the AU480/AU680/AU5800. The limit of detection on the AU480/AU680/AU5800 yielded 8.3 ng/mL. Accuracy was measured using patient correlation against the reference analyzer Hitachi 911, which yielded a Deming’s Regression for each analyzer. (Low Range Cyclosporine): AU480 = 1.03*(Hitachi 911) - 0.40 (N = 115, r = 1.00), AU680 = 0.97*(Hitachi 911) + 13.00 (N = 100, r = 1.00), AU5800 = 1.00*(Hitachi 911) - 0.50 (N = 116, r = 0.99). High Range Cyclosporine: AU480=1.01* (Hitachi 911) + 90.96 (N = 126, r = 0.97), AU680=1.07* (Hitachi 911) + 30.23 (N = 126, r = 0.97), AU5800=1.05* (Hitachi 911) + 9.00 (N = 126, r = 0.97).

Conclusion: All measured studies demonstrated acceptable performance, validating the use of the CEDIA Cyclosporine PLUS Assay on the Beckman Coulter AU480/AU680/AU5800 analyzers, and will provide an effective monitoring system for patients receiving cyclosporine therapy.

 Screening for Hemoglobin Variants [HV]s While Measuring Hemoglobin A1c (HbA1c).

N. Yadak1, C. Hoang2, D. Moore3, E. S. Pearlman3. 1University of Tennessee Health Sciences Center, Memphis, TN, 2Veterans Affairs Medical Center, Memphis, TN

Context: As part of an effort to develop an in-lab protocol for the reporting of HbA1c results in the presence of HVs, we sought to assess the frequency and identities of HVs in the VAMC population.

Methods: Over seven weeks, 518 patients were assayed for HbA1c using HPLC [ Tosoh, South San Francisco, CA] according to manufacturer’s directions. Specimens with an HV flag were referred (Lab Corp; Raleigh, NC) for hemoglobin ID [HbID]. Estimates of the frequency of AS and AC (8 and 2.8% respectively) among African-American [A-A] and the population prevalence of DM (9.5%) are literature derived. A total of 40,648 HbA1c assays were done in calendar year 2012.

Results: A total of 208 (4%) HV flags were generated. The median age was 61 YO [27, 90], 188 (90.4%) were male and 192 (92.3%) A-A while 6 were of unknown race and sex. 427 (89.3%) had diabetes and 227 (45.7%) had hypertension. Patients with AS and AC were assumed to be A-A. The incidence of HVs was 3.3% in A-A and 2.3% in the VAMC. Of the 208 cases, 53 cases were expected to be HVs (90.4% of expected HVs); 28 cases were A2' (51.47%) patients would be tested. Requests were assumed to be uniformly distributed in any 12 month period and the remaining 24,208 assays were attributed to once-tested patients. Thus in any given 12 month period, 29,668 patients out of the total of 57,680 (51.47%) patients would be tested. Requests were assumed to be uniformly distributed over 52 weeks. Making all these assumptions the expected number of AS:A-A patients was [29,668]*[0.035]*[0.008]*[7/52] = 114 [actual=113]. A similar calculation yields an expected 40 instances of AC trait [actual=40]. HbIF and Kokomo specimens generated an HV flag but not a numeric result for HbA1c.

Conclusion: Our population that was 35.7% AA, 4% of patients assayed for HbA1c generated an HV flag. More than 90% occurred in AAs and 85% were S and C trait. Four (2.2%) specimens were NVI. The observed and (crudely) estimated number of AA patients with S and C trait were in close agreement [chi-sq. = 0.084; p > 0.5].
Tubular Damage Is Present In Patients with MGUS and Asymptomatic Multiple Myeloma Even in the Absence of Impaired Estimated Glomerular Filtration Rate; Alterations of Neutrophil Gelatinase-Associated Lipocalin and Cystatin-C in Myeloma Patients Post IMiD- and Bortezomib-Based Regimens

I. Papassotiriou 1, D. Christoulas 2, E. Kastritis 2, G. Papassotiriou 1, A. Margeli, N. Kanellias, E. Eleutherakis-Papaioakou 3, M. A. Dimopoulos 1, E. Terpos 1, 1Department of Clinical Biochemistry, “Aghia Sophia” Children’s Hospital, Athens, Greece, 2Department of Clinical Therapeutics, University of Athens, Medical School, Athens, Greece

Background: We have recently shown that urinary and serum Neutrophil gelatinase-associated lipocalin NGAL were elevated in the vast majority (90% and 70%, respectively) of newly diagnosed patients with multiple myeloma (MM), while serum cystatin-C (CysC), an accurate marker of GFR, was elevated in 70% of them. However, there is no information for the value of these markers in patients with MGUS, asymptomatic MM (AMM), as well as in symptomatic MM post treatment.

Methods and Patients: Thus, we measured urinary and serum NGAL and serum CysC in 40 patients with MGUS, 36 with AMM and 120 healthy controls. Furthermore, we measured serum NGAL and CysC in 39 newly diagnosed symptomatic MM patients before and after frontline therapy with novel agents. Serum and urinary NGAL was measured using an immunoenzymatic technique, while CysC was by means of immunonephelometry. The estimated GFR (eGFR) was calculated using the CKD-EPI equation. Patients were divided into the 5 CKD stages of the K/DOQI classification, according to eGFR.

Results: Urinary NGAL was elevated in patients with MGUS (median: 14ng/ml, range 0.5-31ng/ml) and AMM (22.3ng/ml, 0.9-78ng/ml) compared to controls (5. ng/ml, 0.7-9.9ng/ml, p<0.001 for both comparisons). Similarly, serum NGAL was elevated in patients with MGUS (106ng/ml, 74.9-205.5ng/ml) and AMM (94.2ng/ml, 29.5-306.4ng/ml) compared to controls (63ng/ml, 37-106ng/ml, p<0.001). There was no difference between MGUS and controls or MGUS and AMM regarding CysC serum values, indicating that traditional indices of renal function could not detect early renal damage. However, 22 (55%) patients with MGUS and 24 (66%) with AMM had higher urinary NGAL values than the higher value of the controls. Similarly, 9 (22.5%) MGUS and 11 (30%) AMM patients had higher levels of serum NGAL than the higher value of the controls. The control group consisted of patients with MM that were on maintenance treatment.

Conclusions: We conclude that the high levels of urinary and serum NGAL in MGUS and AMM patients should be monitored in patients with MGUS, asymptomatic MM (AMM), as well as in symptomatic MM post treatment. The high levels of serum NGAL and CysC strongly correlate with eGFR. Thus, NGAL may be useful as an early marker that predicts the development of renal damage and the progression of the disease in these patients. NGAL seems also to increase in patients with renal impairment who receive IMiD-based regimens.

### A-112
Association of Interleukin (IL)-18 -607A/C and -137C/G Polymorphisms With Early Graft Function In Renal Transplant Recipients

H. Akbas, F. Davran, A. Dinckan, H. Kocak, D. Ozel, M. Gultekin, G. Suleymanlar. Akdeniz University, Faculty of Medicine, Antalya, Turkey

Background: Recent studies have suggested that increased levels of IL-18 in serum and renal parenchyma may predict acute rejection in patients with renal transplantation. IL-18 mediates a wide range of inflammatory and oxidative responses including renal injury, fibrosis and graft rejection. It has been reported that the promoter -607 and -137 polymorphisms of IL-18 influence the level of cytokine IL-18 expression. This prospective observational study aimed to assess the relevance of serial postoperative serum/urine creatinine, cystatin C and IL-18 measurements for monitoring early graft function in renal transplant recipients and to evaluate the pro-inflammatory property of IL-18 by measurement of serum IFN-γ and CRP. We also determined the effect of IL-18 -607 A/C and IL-18 -137 C/G polymorphisms on graft function.

Methods: This study included 75 renal transplant recipients (28 female, 47 male; mean age: 38.28 ± 13.03) from living related donors. Blood and urine samples were collected immediately before and after transplantation at day 7 and month 1. Serum IFN-γ, IL-18, creatinine, cystin C, CRP and uramn IL-18, cystatin C and creatinine levels were measured. Polymorphisms of the promoter region of the IL-18 gene, IL-18 -607A/C and -137C/G were determined by analysis of “real-time PCR/Melting curve”. GFR values were estimated by Modified Diet in Renal Disease (MDRD), Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) and some cystatin-C-based formulas (Larsson, Rule, Hoek). SPSS 20.0 software was used for statistical analysis.

Results: Serum creatinine, cystatin C, CRP, IFN-γ, IL-18, urine cystin C levels and urine cystatin C/creatinine, urine IL-18/creatinine ratios were significantly decreased after transplantation (p<0.005). Serum cystin C and IL-18 levels were significantly higher in patients with IL-18-607 CC genotype before transplantation. While pretransplant levels of serum creatinim and IL-18 were found significantly higher in patients with IL-18-607 CC genotype, we also observed significantly higher serum IFN-γ levels and estimated GFR (MDRD and CKD-EPI) values in CA genotype (p<0.012). Receiver operating characteristic (ROC) analysis was performed to quantitate the accuracy of the different markers to detect changes in GFR. Posttransplant serum creatinine and cystatin C demonstrated a significantly greater AUC (area under the curve), sensitivity and specificity values than IL-18 and IFN-γ.

Conclusion: In this study, although we observed significantly differences in serum IL-18 levels and some GFR markers according to genotypes, the influence of polymorphisms on early graft function has not been clearly shown. Future larger studies are needed to confirm the association of cytokine gene polymorphisms with graft function. Prior to transplantation, screening of genetic predisposition which may have deleterious effect on graft function could lead to the development of new treatments for better graft survival and ultimately improve the outcome of renal transplantation.

### A-113
May routine urine analysis reduce the number of unnecessary culture requests?

Background: Urinary Tract Infection (UTI) is the most common bacterial infection in the society. Bacterial infections can lead to the leukocytosis. Urine analysis is one of the most common tests for assessing urinary-tract infections. Urine culture is still the ‘gold standard’ for the detection of urinary tract infection, however, it is time- and labor-intensive and has a high number of unnecessary cultures. The aim of this study was to evaluate diagnostic performance of infection-related (associated) parameters of urine preliminary analysis (leukocyte esterase, nitrite, bacteria and leukocyte) in comparison to urine culture as the reference method and to investigate whether the performance of UTI cause leukocytosis.

Methods: The electronic database of our laboratory was searched between July 2013 and December 2013. Our hospital is a tertiary central hospital with 671 beds. Approximately 239,029 urinalyses were requested while the majority of these requests were from outpatients and emergency patients. A total of 3427 patients (1980 women, 1447 men, mean age 49.2±18.42) which were request unirnalysis, CBC and urine culture on the same day were enrolled in the study. All results were retrospectively reviewed. Leukocyte esterase and nitrite in chemical analysis were measured with fully automatic urine analyzer (IRIS IQ200 Diagnostics, USA). Pyuria (WBC) and bacteria in microscopy, leukocyte of CBC (Beckman Coulter LH1870, USA) parameters were compared with urine culture. Diagnostic performance of parameters for detection of UTI were evaluated.

Results: Urine cultures were positive in 413 patients (%11.9). E. coli was the most frequently isolated bacteria (70.4%). Ratios of positive dipstick results for leukocyte esterase and nitrite in culture positive patients were 85% (n=352) and 40 % (n=166) respectively. The positive microscopy results for bacteria and leukocyte were 31 % (n=127) and 75 % (n=310), respectively. Positive predictive values of leukocyte esterase, nitrite, pyuria and bacteria tests were 69 %, 97 %, 74 %, and 91 % while negative predictive values were 80 %, 62 %, 75 %, 58 % respectively. The highest specificity rate was nitrite (99 %). Leukocytosis rate in patients with a positive urine culture was 23 % (n=96). A relatively high correlation was found between LE and microscopic WBC count (r = 0.827; P < 0.001).

Conclusions: Routine urine analysis is thought to be reliable in preliminary diagnosis of UTI and start empirical treatment without waiting for culture results. Also urine

Enhanced Liver Fibrosis (ELF) Score indicates progressive fibrosis in pre-clinical stages of Primary Biliary Cirrhosis

D. C. Baldo1, A. Dellavance2, F. Latini2, J. A. Barreto2, N. R. França1, L. E. C. Andrade1. 1Fleury Medicine and Health, São Paulo, Brazil, 2Beneficent Association of Blood Collection from Sao Paulo, São Paulo, Brazil, 3Universidade Federal de São Paulo, São Paulo, Brazil

Background: Liver fibrosis is a common consequence of most chronic liver diseases. The assessment of liver fibrosis is usually made by histologic analysis of liver biopsy samples. Puncture liver biopsy has inherent risks to the patient. Primary biliary cirrhosis (PBC) is a slowly progressive cholestatic disease associated with the development of cirrhosis and liver failure that may justify liver transplantation. PBC diagnosis is based on completion of at least two of the following criteria: characteristic histological findings; elevated alkaline phosphatase serum levels for over six months; and circulating anti-mitochondria autoantibodies (AMA). AMA is detected in roughly 95% of PBC patients, with a specificity of at least 98%. Occasionally AMA-positive (AMA+) subjects with normal liver enzymes are identified by characteristic cytoplasmic pattern in the regular antinuclear antibody indirect immunofluorescence assay on Hep-2 cells. Biochemically normal (BN) AMA-positive individuals may represent earlier stages of CBP and may require confirmation by liver history analysis. The Enhanced Liver Fibrosis (ELF) score is an alternative approach that combines three serum markers in an algorithm to generate a score correlated with liver fibrosis status, as assessed by ELF score, in BN-AMA-positive individuals along a 4.5-year follow-up period.

Methods: ELF score was determined for 37 PBC patients, 68 BN-AMA-positive individuals, and 172 age- and gender-matched blood donors. BN-AMA-positive individuals and PBC patients had two samples obtained 4.57 (1.37 - 16.04) and 4.75 (1.91 - 8.37) years apart, respectively. ELF score was calculated according to a pre-established algorithm based on the serum levels of hyaluronic acid, procollagen III and inhibitor of metalloproteinase determined by chemiluminescence (Siemens Healthcare Diagnostics).

Results: ELF score was higher in baseline PBC samples (mean 9.63; 95% CI: 9.09-10.17) than in baseline BN-AMA-positive samples (9.14; 95% CI: 8.92-9.37) (p=0.038) and blood donor samples (8.91; 95% CI: 8.81-9.02) (p=0.001), with no significant difference between BN and blood donors (p=0.284). There was a significant increase in ELF score in the follow-up of PBC patients (p=0.010) and BN-AMA-positive individuals (p=0.001).

Conclusion: PBC patients presented evidence of more severe liver fibrosis than BN-AMA-positive individuals did. The progression in liver fibrosis status in BN-AMA-positive individuals along the years indicates a subclinical inflammatory process in these individuals. ELF score appears to be a sensitive parameter for evaluation of the progression of liver involvement in BN-AMA-positive individuals.

Cardiac troponin I and B-type natriuretic peptide predict clinical outcomes in stable renal transplant recipients

P. Jarolim1, B. L. Claggett4, M. A. Pfaffer1, A. Ivanova2, M. A. Carpenter2, A. G. Bostom4, J. W. Kuske4, L. G. Hunsicker1, P. F. Jacques5, L. Gravens-Mueller1, P. Finn4, M. J. Conrad4, S. Solomon4, A. S. Levy4. 1Bigham and Women’s Hospital, Harvard Medical School, Boston, MA, 2University of North Carolina, Chapel Hill, NC, 3Rhein Island Hospital, Providence, RI, 4National Institute of Diabetes and Digestive and Kidney Disease, Bethesda, MD, 5University of Iowa, Iowa City, IA, 6US Department of Agriculture, Jean Mayer Human Nutrition Research Center on Aging, Boston, MA, 7Tufts Medical Center, Boston, MA

Background: Cardiac troponins and natriuretic peptides are becoming established as predictors of clinical outcomes (CO) in patients with cardiovascular (CV) disease; however their value in renal transplant recipients has not been established. Methods: Using a case-cohort design, we tested baseline specimens from 1114 stable renal transplant recipients enrolled in the FAVORIT study (The Folic Acid for Vascular Outcome Reduction In Transplantation) using the B-type natriuretic peptide (BNP) and high sensitivity troponin I (hsTnI) assays (both Abbott). CO included all-cause death, dialysis-dependent kidney failure (DDKF) and CV outcomes. The relationship between BNP and hsTnI values and CO were assessed via Cox regression models. Quartiles (Q) of the two biomarkers were included in models adjusted for age, gender, race, treatment, history of smoking, coronary heart disease, diabetes mellitus, A/C ratio, eGFR, BMI, blood pressure, lipid levels, graft vintage and donor type. Combinations of Q4 of BNP and hsTnI (BNP high, hsTnI high) and Q1-3 of BNP and Tnl (BNP low, hsTnI low) were also evaluated. Results: Median concentrations and interquartile ranges for Tnl and BNP were 5.6 (3.3, 10.5) ng/L and 56 (22, 129) ng/L. Both BNP and Tnl levels were associated with age, donor type, history of CHD and diabetes mellitus, systolic BP, eGFR and urine ACR. Hazard ratios (HRs) for each fatal and non-fatal endpoint increased significantly with increasing quartiles of BNP after adjustment and remained significant after adding Tnl to the model. HRs for the BNP/Tnl combinations were strongly associated with all CO studied (Table).

Conclusion: BNP is predictive for death, CV as well as renal outcomes in stable renal transplant recipients. Simultaneous elevation of BNP and Tnl is relatively common and strongly predictive of CO.

Results of Sample Testing for the Determination of Reference Intervals in Apparently Healthy Pediatric Subjects for ADVIA Centaur® Systems, Dimension Vista® and Dimension EXL® Systems Thyroid Assays

R. H. Christenson1, D. Counts1, B. Plouffe2, S. Gafary3, R. Levine2, T. Sullivan1. 1The University of Maryland, Baltimore, MD, 2Siemens Healthcare Diagnostics Inc., Tarrytown, NY, 3Norwich Pediatric Group, Norwich, CT

Background: Age-specific reference intervals are necessary for appropriate interpretation of thyroid hormone measurements in the pediatric population and may vary due to methodological differences. A challenge for establishing pediatric reference intervals has been the availability of well-characterized samples from healthy pediatric subjects. Of the few studies that provide this information, most are based on specimens from patients who were hospitalized or required medical care. This study used methodology consistent with CLSI guidelines to pedigree and collect samples from apparently healthy pediatric subjects presenting for regular well child care.

Objective: To test well-characterized specimens from healthy pediatric subjects to establish pediatric reference intervals for various assays and instruments.

Methods: Eight US sites prospectively collected samples from apparently healthy pediatric subjects, under institutionally approved consent/assent procedures. Subjects were normal according to CDC weight- and height-based growth charts, were free of chronic and acute diseases, were not on medication, had no family history of thyroid dysfunction, no visible or palpable goiters, and were negative for anti-thyroglobulin and anti-thyroid peroxidase antibodies. Three age subgroups were analyzed with the characteristics and strongly predictive of CO.

Evaluation of six different formulas and equations for estimate low density lipoprotein cholesterol (LDLc) concentration.

Background: The National Cholesterol Education Program Adult Treatment Panel (ATP III) identified the serum LDLc concentrations as the primary criterion of diagnosis and treatment of patients with hyperlipidemia and also as one of the most important parameter for evaluation of coronary heart disease and cardiovascular risk assessment. Most of Peruvian clinical laboratory used the Friedewald formula and some LDLc precipitate method for estimate serum LDLc concentration, but the Friedewald formula used has some limitations especially with extreme low and high triglycerides values (> 400 mg/dL). The aim of the study was to estimate LDLc from serum samples using two different method: Friedewald and Friedewald formula with enzymatic colorimetric endpoint method (Wiener Lab, Argentina), using a BT 3000 Plus automatic photometer analyzer at the Clinical Laboratory of Cayetano Heredia Clinic - Universidad Peruana Cayetano Heredia.

Methods: A descriptive cross-sectional study was conducted and 220 serum samples from adolescent students of medical technology at the Peruvian University Cayetano Heredia were collected during the annual clinical evaluation performed on November 2012. Serum samples on fast conditions for lipid profile were obtained, the measurement of LDLc cholesterol and HDLc cholesterol were performed by precipitation methods (Wiener Lab, Argentina), Total Cholesterol (TC) and Triglycerides (TG) were measurement by enzymatic colorimetric endpoint method (Wiener Lab, Argentina), using a BT 3000 Plus automatic photometer analyzer at the Clinical Laboratory of Cayetano Heredia Clinic - Universidad Peruana Cayetano Heredia. Linear regression analysis and Blant Altman plots were performed to evaluate six different formulas and equations for LDLc estimation and compared to LDLc precipitate method using MS Excel and MedCalc Statistical Software. TG and LDLc obtained values for the statistical analysis and clinical classification were divided in levels according to ATP III.

Results: Linear regression and Blant Altman plots showed a significant correlations and agreements, respectively. The correlation coefficient for serum sample group of TG ≤ 149 mg/dL were to Friedewald, Chen, Pauviliai, Vujevic (R²=0.95), Cordova (R²=0.94), Anandaraja (R²=0.81), respectively. For serum sample group of TG between 150-199 mg/dL were Friedewald, Pauviliai, Vujevic (R²=0.88) and Cordova (R²=0.91), whereas TG (200-400 mg/dL) Friedewald, Chen, Anandaraja, Vujevic (R²=0.87) and Cordova (R²=0.86). Using Friedewald formula n=18 (8.18%), Anandaraja n=30 (13.63%), Chen n=44 (20%), Vujevic n=14 (6.36%), Vujevic n=24 (10.91%) and Cordova n=106 (48.18%) patients show a probably misclassification for hyperlipidemia. Conclusion: Six different formulas showed significant correlations and agreements according Linear regression analysis and Blant Altman plot. The Pauviliai equation/formula showed good performance to estimate LDLc in all triglycerides levels and shows less misclassification of patients for hyperlipidemia compared to LDLc precipitate method used in this study.

A Hope for Healing Using Amniotic Membrane and Stem Cells

A. O. B. S. Osman1, M. M. S. El Ansary2, H. G. Metwally3, A. A. Gad4, H. G. Al-Inany5, A. H. B. Elbadawy6. 1Misr University for Science and Technology, Faculty of Medicine, Cairo, Egypt, 2Cairo University, Faculty of Medicine, Cairo, Egypt, 3Cairo University, Faculty of Medicine, Cairo, Egypt, 4Assuit University, Faculty of Medicine, Assuit, Egypt

Objectives: Testing a new technique for treatment of chronic non-healing ulcers using amniotic membrane (AM) alone or in combination with autologous mesenchymal stem cells (MSCs) as an application of clinical laboratory medicine in regenerative medicine. Methodology: After Institutional Ethical Committee approval, each patient signed informed written consent. The study was conducted on 73 chronic leg ulcers. Patients were randomly divided into 4 groups: Group I (control group, 14 ulcers), ulcers were treated with conventional wound dressings that were changed every day for 8 weeks; Group II (14 ulcers) AM was placed in contact with ulcer and held in place with 2ry dressing; which was changed every day; Group III (6 ulcers) autologous BM derived MSCs were injected into ulcer bed and ulcer edges; Group IV (6 ulcers) Autologous MSCs were injected into ulcer bed and ulcer edges, and freshly prepared AM was placed in contact with ulcer and held in place with 2ry dressing

Patients were subjected to: Assessment of ulcer healing and wound measurement; 1. Percentage of the healed wound area and healing rate; healed wound area=(Original wound size-final wound size) (Original wound size×100 Healing rate in cm²/day)= (Original wound size-final wound size) /Time consumed to reach final wound size. Wound size: Greatest length and greatest width were measured, and surface area was calculated in cm². 2. Wound grading: Based on Pressure Ulcer Scale for Healing (PUSH Tool) Ulcers classified as Mild, Moderate, and Severe. 3. Pain Assessment. On a scale from 1 to 10, pain level is classified as (No pain, Mild, Moderate, & Severe). 4. Full Group: Healing rate and ulcer size. Pain assessment - Taken of AM graft (Day2) Ulcer images (Day0) and weekly till end of the study: Statistical Analysis. It was performed with SPSS software version15.0 for windows (SPSS Inc., CR). Results: Significant improvement in patients of groups II, III, and IV regarding pain & ulcer size. There was significant difference in healing rate & reduction in ulcer size between group I and (group II & IV) with (P<$0.001) where wounds showed an overall decrease in wound size and improvement in wound bed with healthy granulations. Group II results showed complete healing of 14 ulcers in 14-60 days with mean of 33.3±14.7, healing rate was 0.064–2.22 and mean of 0.896 ±0.646 cm²/day with 100% reduction in ulcer size. In group III, 4 ulcers (66.7%) showed complete healing in 45-60 days with mean of 50.5±6.7, while 2 ulcers (33.3%) showed partial healing with healthy granulations. Ulcers’ healing rate was 0.084 – 0.787 cm²/day, with mean of 0.303 ±0.254. Reduction in ulcer size ranged from 50.4% to 100%, with mean of 83.9% ±24.9%. In group IV- in the combined treatment with AM and autologous MSCs- 3 leg ulcers (50%) showed complete healing in 14- 25days with mean of 17.7±6.35 and 3 ulcers (50%) showed partial healing with healthy granulations. Range of Ulcers’ healing rate was 0.359–1.23 cm²/day with mean of 0.759 ±0.361. Range of reduction in ulcer size in group IV was 46.5% – 100%, and mean of 78.95%±24.2%. Conclusion: Using AM alone or in combination with autologous MSCs represents promising simple, safe, effective, and novel therapeutic approach for closing and healing of persistent non-healing chronic leg ulcer.

Inflammatory Markers in Polycystic Ovary Syndrome

G. Ozturk1, S. Ozdemir2, O. Ozdemir2, D. Kalkan2, G. Edeer2, S. Sezer2, C. R. Atalay2. 1Ankara Diskapi Yildirim Beyazit Research and Training Hospital, Department of Clinical Biochemistry Ankara, Turkey, 2Ankara Numune Research and Training Hospital, Department of Obstetrics and Gynecology Ankara, Turkey.

Background: Previous studies have demonstrated polycystic ovary syndrome (PCOS) associated with a proinflammatory state. The clinical spectrum of PCOS includes components of the metabolic syndrome, such as central obesity, insulin resistance, dyslipidemia and hypertension. All these disorders are epidemiologically related to cardiovascular disease, most probably through low-grade intravascular chronic inflammation. We aimed to investigate whether inflammatory markers, including C-reactive protein (CRP), procalcitonin and ischemia modified albumin (IMA) are related and altered in polycystic ovary syndrome.

Methods: A case-control study including fifty women diagnosed with PCOS,
Tuesday, July 29, 9:30 am – 5:00 pm

Recommendations of U.S. Preventive Services Task Force for Health Screenings that Include Use of Laboratory Tests

S. Shahangian1, V. A. Moyer2. 1CDC, Atlanta, GA. 2U.S. Preventive Services Task Force, Chapel Hill, NC

Background: Health screening tests greatly impact the public’s health because they involve testing of asymptomatic populations for diseases or conditions where interventions may impact health outcomes. U.S. Preventive Services Task Force (USPSTF) is the leading independent panel of experts that conducts rigorous and impartial assessments of scientific evidence for effectiveness of clinical preventive services. Methods: All screening recommendations are rated by USPSTF into 1 of 5 grades: ‘A’ for strong recommendation with high certainty that net benefit is substantial, ‘B’ for recommendation with high certainty that net benefit is moderate or moderate certainty that net benefit is moderate to substantial, ‘C’ for individualized decision making with at least moderate evidence that net benefit is small, ‘D’ against screening with moderate to high certainty that net benefit is zero or harms outweigh benefits, and ‘I’ is a statement that no recommendation can be made due to insufficient, poor quality, or conflicting evidence, with the balance of benefits and harms of screening undetermined. Results: Laboratory screening tests for 35 diseases/conditions have been included in USPSTF’s evaluations for different target populations, resulting in a total of 60 currently active recommendations for laboratory testing. Of these, there were 20 ‘A’ and 20 ‘B’ recommendations including: cervical cancer in women aged 30-65 years; chlamydial infection in sexually active women aged ≤24 years and older pregnant women at risk; colorectal cancer in adults aged 50-75 years; diabetes mellitus in adults with sustained hypertension, gonorrhea infection in sexually active women at increased risk, hepatitis B virus (HBV) infection in pregnant women; hepatitis C virus infection of persons at high risk and 1-time screening of those born in 1945-1965; HIV screening of pregnant women, 1-time HIV screening of adolescents and adults aged 15-65 years; risk of coronary heart disease in men aged ≥55 years, as well as both men and women aged ≥55 years who are at increased risk; and syphilis infection in pregnant women. The most common recommendation grades were D and I (17 each). D recommendations included: cervical cancer in women aged ≥21 years; those aged ≥65 years not at high risk and with adequate prior screening, those with hysterectomy leading to removal of cervix and no history of high-grade or cancerous lesion, and human papilloma virus screening of women aged <30 years; colorectal cancer in adults aged ≥85 years; genital herpes simplex virus infection in adults, pregnant women, and adolescents; gonorrhea infection in men and nonpregnant women at low risk for infection; HBV infection in men and nonpregnant women; hereditary hemochromatosis in adults; lead poisoning in children aged 1-5 years at average risk and pregnant women; ovarian cancer in women excluding those with known genetic mutations that show increased risk; pancreatic cancer; prostate cancer; and syphilis infection in nonpregnant persons not at increased risk. Conclusion: While common perception is that screening is recommended for major and prevalent diseases, the USPSTF either recommended against (28%) or insufficiently supported (28%) use of more than half of the evaluated laboratory markers.

Clinical Studies/Outcomes

A-122

Performance of the Elecsys® Vitamin D Assay in a Multicenter Evaluation

A. Algeciras-Schimniel1, A. A. Valcuere2, P. Jarolim3, M. Lessig4, J. Kappes5. 1Mayo Clinic, Rochester, MN. 2LabCorp, Burlington, NC. 3Brigham and Women’s Hospital, Boston, MA. 4NLS Lab Director/Nationwide Labs, Fort Lauderdale, FL. 5Roche Diagnostics Operations, Indianapolis, IN

Background: Increased awareness and investigation into the importance of vitamin D for many physiological processes has resulted in dramatically increased demand for vitamin D testing. New automated methods to measure 25-hydroxyvitamin D (25-OHD) levels have been developed to help laboratories accommodate this surge. The fully automated Roche Elecsys® Vitamin D assay, which allows for the quantitative determination of total 25-OHD in human serum and plasma, was recently introduced to the US market. The Elecsys Vitamin D assay is standardized against a liquid chromatography-tandem mass spectrometry (LC-MS/MS) method using National Institute of Standards and Technology (NIST) reference materials for calibration. The current study evaluated the performance of the Elecsys Vitamin D assay across several laboratories in the United States to determine its suitability for use in clinical practice. Functional sensitivity, imprecision, and clinical concordance with a well-established NIST standardized LC-MS/MS method were assessed. Methods: Functional sensitivity was assessed using 8 pooled samples covering a range of 0-16 ng/mL, which were tested once a day for 10 consecutive days. Precision was assessed following CLSI EP5-A2/EP15-A2, from 5 pooled samples in the 10- to 50-ng/mL range. Deming regression analysis was used to compare the results of the Elecsys Vitamin D assay obtained at 2 sites on the cobas e411 analyzer with LC-MS/MS performed at Mayo Clinic. Four sample cohorts were used: subjects referred for routine vitamin D testing were included in cohort I, while predialysis patients (cohort II), pregnant women (cohort III), and patients in the intensive care unit (cohort IV) represented unique subpopulations. The clinical performance of the 2 methods was evaluated using 20-ng/mL and 30-ng/mL cutoffs for vitamin D sufficiency. Results: The functional sensitivity of Elecsys Vitamin D, assessed at 2 sites, was 3.52 ng/mL and 3.37 ng/mL with coefficient of variation (CV%) of 15% and 16%, respectively. Elecsys Vitamin D demonstrated consistent reproducibility across lots (N=2), across the 2 sites tested, with CV% of 5.66% to 7.12% (SD for concentrations below 15 ng/mL: 1.40 ng/mL). Consistent repeatability (CV% of 1.30% to 5.48% [0.40 to 0.72 ng/mL]), within site/lot precision (CV% of 1.94% to 7.47% [0.49 to 1.26 ng/mL]), and within site/across 2 lots precision (CV% of 4.06% to 7.78% [1.00 and 1.10 ng/mL]) was demonstrated. Overall, acceptable consistency between Elecsys Vitamin D assay at both sites, and LC-MS/MS was observed for regression parameters in both the routine and specialty cohorts with a slope range of 1.03 to 1.22 and Pearson’s r range of 0.857 to 0.932. The LC-MS/MS sufficient/insufficient classification based on the 20-ng/mL cutoff over cohort I (routine adults) was 67.3% sufficient/32.7% insufficient compared with 68.8%/31.2% observed with the Elecsys method at 1 site. Using the 30-ng/mL cutoff over cohort I, the LC-MS/MS classified 36.7%/63.3% as sufficient/insufficient, respectively, and the Elecsys showed agreeable numbers at 38.3%/61.7%. Conclusion: The Elecsys Vitamin D assay showed robust technical performance, with good functional sensitivity and low imprecision. Analysis of multiple cohorts showed high clinical concordance with NIST standardized LC-MS/MS, supporting the suitability of the assay for use in clinical practice.

A-123

Homogeneous immunoassay for estradiol based on blue-emitting upconverting nanophosphors and luminescence resonance energy transfer

V. Kale, L. Mattsson, R. Arppe, T. Soukka. University of Turku, Turku, Finland

Objective: The purpose of this study was to demonstrate a competitive homogeneous assay for 17β-estradiol (E2) based on photon upconversion luminescence. NaYF₄:Yb,Tm upconverting nanophosphor (UCNP) with strong emission at 475 nm under 980 nm excitation was used as a donor in upconversion luminescence resonance energy transfer (UC-LRET) with small molecular conventional fluorescent dyes energy acceptors.

Methods: Upconverting nanophosphors (UCNPs; NaYF₄; 20% Yb, 0.5% Tm) of 25-30 nm in size were synthesised using oleic acid as chelating agent and shape modifier. The nanophosphors functionalized silica shell comprising carboxylic acid groups, which were covalently conjugated to anti-E2 Fab antibody fragments (Fab S16) using carbodiimide chemistry. E2 conjugated Alexa Fluor 488 (I2-AF488) and fluorescein isothiocyanate (E2-FTTC) dyes were used as acceptor conjugates. The luminescence
spectrum of the donor (emission peak around 475 nm) overlapped with the excitation spectrum of the acceptors. In the homogeneous E2 assay, E2 dilutions were buffer first incubated together with the Fab S16 coated upconverting donor, then E2-AF 488 or E2-FITC were added to the reaction and the sensitized acceptor emission was measured at 565 nm with anti-stokes luminescence plate reader (Hidex Oy, Turku, Finland) under 980 nm infrared excitation.

Results: By using 0.006 mg/ml UCNP donor with 16 nM E2-AF488 acceptor conjugate or 0.01 mg/ml UCNP donor with 4 nM E2-FITC acceptor conjugate in the assay reaction, standard curves with IC50 values of 2 nM and 1.7 nM were obtained, respectively. The working range of the assay was from 0.80 nM to 3.10 nM E2 concentrations with both the acceptors. Signal levels for the homogeneous assay using the E2-FITC acceptor conjugate were two times higher than by using the E2-AF488 acceptor conjugate. However, the ratio between maximum and minimum signals, or the signal-to-background ratio, was 12 for E2-AF488 and 8 for E2-FITC acceptor.

Conclusions: In this study, we introduced a blue emitting upconverting nanophosphor as an efficient donor in UC-LRET and demonstrated a competitive homogeneous upconversion based immunoassay for E2. Photon upconversion and luminescence resonance energy transfer enable sensitive homogeneous immunoassays, which eliminate the autofluorescence background with simple instrumentation and render UCPS an attractive reporter technology for clinical diagnostic.

A-124
Enhanced Liver Fibrosis (ELF) Score for the Evaluation of Liver Fibrosis in Autoimmune Hepatitis
E. Oliveira1, R. M. Perez2, P. M. Oliveira1, A. Dellowance, L. E. C. Andrade2, M. L. Ferraz3. 1Federal University of Sao Paulo, Sao Paulo, Brazil, 2Federal University of Rio de Janeiro, Rio de Janeiro, Brazil, 3Fleury Medicine and Health, Sao Paulo, Brazil

Background: Evaluation of fibrosis is very important in chronic liver diseases, in order to define prognosis and therapeutic options and to establish strategies of follow-up. Until now, the ELF score has been considered the gold-standard for the evaluation of fibrosis. However, it is an invasive method and prone to sampling error. These problems have motivated the search of non-invasive and more reliable methods for detecting and staging liver fibrosis. The ELF (Enhanced Liver Fibrosis) score is based on an algorithm of three markers: (hyaluronic acid, pro-collagen III e inhibitor of metallocproteinase 1) and has been evaluated in different etiologies of liver diseases. However, ELF score has not yet been evaluated in patients with autoimmune hepatitis (HAV). Aim: to evaluate the performance of ELF score in patients with AIH, using the liver biopsy as a gold-standard.

Methods: Patients with HAI and a liver biopsy performed in less than 12 months were included and had a serum sample collected for the ELF score (Siemens Healthcare Diagnostics). Patients with hepatitis B or C were excluded, as well as patients with alcohol consumption > 20 g/day.

Results: 105 patients were evaluated and 89 were included (90% female, mean age 34y). According to the ELF cut-offs proposed by the manufacturer, 8% of patients had absent/mild fibrosis, 42% moderate fibrosis and 50% advanced fibrosis. ELF score overestimated fibrosis in 28% of cases and underestimated in 33%. The accuracy of ELF (AUROC) for significant fibrosis (F ≥ 2) was 0.64 (CI 95%: 0.52-0.77; p= 0.05), for advanced fibrosis (F ≥ 3) was 0.59 (CI 95%: 0.47-0.71; p = 0.17) and for cirrhosis was 0.66 (CI 95%: 0.54-0.77; p= 0.009). Coefficient of correlation for ELF and liver biopsy was 0.24 (p=0.02), for periportal necroinflammatory activity was 0.28 (p = 0.009) and for lobular necroinflammatory activity was 0.43 (p = 0.001).

Conclusion: ELF score had not a good performance as a marker of liver fibrosis in patients with AIH. Using proposed cut-offs, there was overestimation as well as underestimation of liver fibrosis in many cases when comparing to liver biopsy. It is possible that the biomarkers included in the ELF score could have been influenced by the intense necroinflammatory process observed among AIH patients. In fact, ELF score was more intensely associated to lobular activity (p = 0.001) then to liver fibrosis (p = 0.22). It is interesting to note that 4 patients with acute hepatitis and no fibrosis had a high ELF score, confirming that intense inflammation is a relevant confounder of indirect liver fibrosis assessment.

A-125
Organisms cultured from the synovial fluid of infected prosthetic joints.
P. Kilmartin2, S. Gulati2, P. Citrano2, K. Kardos1, C. Deimengian1. 1CD Diagnostics, Inc, Wynnewood, PA, 2Citrano Medical Laboratories, Towson, MD

Objective: Prosthetic joint infection (PJI) occurs after primary joint replacements at a rate of 1.0-3.0% and after revision joint replacements at a rate of 2.0-20.0%. Synovasure™ is a laboratory developed test (LDT) for the detection of alpha-defensins in the synovial fluid (joint fluid), which have been shown to be elevated in infected samples. There are two main objectives of this study: first to describe the variety and distribution of organisms infecting joint replacements nationally, and second to evaluate for organism-specific differences in the synovial fluid alpha-defensin level.

Methods: 1698 synovial fluid specimens from 40 states were sent to our laboratory for the Synovasure™TM alpha-defensin assay and were also cultured using the BacT/ALERT® FAN FA/FN culture bottles for recovery of aerobic and anaerobic organisms (Biomerieux). The organisms were identified and evaluated for susceptibilities using the VITEK® 2 ID/AST system (Biomerieux), a fully automated system that provides rapid microbial identification and susceptibility testing.

Results: 47 different organisms from 237 culture-positive samples were identified (distribution summarized in graph). The data indicate that Staphylococcus epidermidis and Staphylococcus aureus account for 46% of the organisms cultured. Of S. aureus isolates, 41% were methicillin-resistant. In addition, there were no statistically significant organism-specific differences in the synovial fluid alpha-defensin levels in the culture-positive samples.

Conclusion: In a large national survey, we have identified Staphylococcus epidermidis (33%), Staphylococcus aureus (33%) and Staphylococcus lugdunensis (6%) as the most common organisms isolated from synovial fluid. The 40% rate of methicillin-resistance among S. aureus isolates is quite concerning given the poor outcomes associated with the treatment of these prosthetic infections. The elevation of alpha-defensin in the synovial fluid of infected joint arthroplasties does not appear to be influenced by the organism type.

A-126
Predictive roles of N-terminal proBNP and high sensitive Troponin T levels in determining mortality in chronic renal failure patients
S. Ozdem1, V. T. Yilmaz2, G. Uzun1, L. Donmez3, S. S. Ozdem4, G. Suleymanlar2, R. Cetinkaya2, F. Ersoy2. 1Akdeniz University Medical School, Department of Biochemistry, Antalya, Turkey, 2Akdeniz University Medical School, Department of Internal Medicine, Division of Nephrology, Antalya, Turkey, 3Akdeniz University Medical School, Department of Public Health, Antalya, Turkey, 4Akdeniz University Medical School, Department of Pharmacology, Antalya, Turkey

Background: The mortality in chronic renal failure (CRF) patients is higher than that in normal population. Cardiovascular events are the major contributors in increased mortality rate in CRF patients since more than 50% of deaths are due to cardiovascular events. Cardiac troponins are highly specific and sensitive markers of myocardial damage. Increments in troponin levels in CRF are related to adverse clinical outcomes. B-type natriuretic peptide (BNP) is a cardiac neurohormone predominantly released from the ventricles in response to left ventricular volume expansion and pressure overload. It is released as a prohormone and is cleaved into proBNP and a signal peptide. ProBNP is subsequently cleaved into BNP and the inactive N-terminal proBNP (NT-proBNP) peptide. Levels of BNP or NT-proBNP are known to be elevated in patients with left ventricular dysfunction. BNP may serve as an important plasma biomarker for cardiac stress and ventricular hypertrophy in patients with CRF. In fact, elevated levels of BNP indicate an increased risk of cardiac events and mortality in patients undergoing peritoneal dialysis. Markers with capacity to identify CRF patients with high mortality risk early in the course of disease may help in clinical management of these patients improving outcomes. In the present study we investigated the predictive values of NT-proBNP and high sensitive Troponin T (hsTNT) levels separately and in combination in determining all-cause mortality in CRF patients on peritoneal dialysis.
Methods: A total of 51 CRF patients (21 female, 30 male, mean age: 50.9 ± 16.5 years) and 41 healthy control subjects (22 female, 19 male, mean age: 45.7 ± 11.6 years) were included in the study. Serum levels of NT-ProBNP and hsTnT (ECLIA method) were measured in all study subjects. Optimal prognostic cut-off points for NT-ProBNP and hsTnT were determined. Overall survival rates were determined by using the Kaplan-Meier method with log-rank test for comparison among groups with different cut-off points of NT-ProBNP and hsTnT.

Results: CRF patients had significantly higher levels of NT-ProBNP (5382.0 ± 1115.0 vs 77.00±9.99 pg/mL, P < 0.00001) and hsTnT (0.070 ± 0.010 vs 0.004 ± 0.001 ng/mL, P < 0.0001) than control subjects. Of the 51 patients enrolled, 24 died and 27 survived during a median follow-up period of 56.4 months (P25-P75: 32.3-57.3). Optimal prognostic cut-off points for NT-ProBNP and hsTnT were ≥ 1950 pg/mL and ≥ 0.050 ng/mL, respectively. Patients with elevated hsTnT levels had higher risk than patients with elevated NT-ProBNP levels when compared with the group which had low levels of both markers (HR 4.00 [95% CI, 1.57-10.20], P < 0.004 and HR 3.31 [95% CI, 1.40-7.82], P = 0.006, respectively). Patients with elevated levels of both hsTnT and NT-ProBNP had a markedly increased all-cause mortality risk (HR 10.38 [95% CI, 2.82-38.27], P < 0.0001).

Conclusion: Our results have demonstrated for the first time that determination of both hsTnT and NT-ProBNP levels is better at predicting CRF patients with high mortality risk than determination of either biomarker alone.

Enhanced Liver Fibrosis (ELF) Score for the Evaluation of Liver Fibrosis in Schistosomiasis Mansoni

T. B. Medeiros 1, A. L. C. Domingues 1, E. P. Lopes 1, A. Dellavance 2, L. E. C. Andrade 2, M. L. Ferraz 1. 1Federal University of Pernambuco, Recife, Brazil, 2Fleury Medicine and Health, São Paulo, Brazil, 3Federal University of São Paulo, São Paulo, Brazil

Background: Schistosomiasis mansoni has a worldwide distribution and affects over 70 million people, constituting a major cause of fibrogenic liver disease. The assessment of periportal fibrosis by ultrasound is the gold-standard for staging fibrosis in patients with schistosomiasis. However, although simple and non-invasive, ultrasound examination is not always available in endemic areas. Aim: To correlate the ELF score with patterns of periportal fibrosis obtained by ultrasoundography in patients with Schistosomiasis mansoni.

Methods: Patients of both genders, aged ≥ 14 years, coming from an endemic area for schistosomiasis with a history of exposure to contaminated water were included. An ultrasoundography was performed by a single examiner, with unit Siemens Acuson X 150 with 3.5 MHz convex transducer. Periportal fibrosis was classified according to the six patterns of Niameye (graded from A to F, with A = no liver fibrosis and F = very advanced fibrosis). Exclusion criteria were the presence of serum markers of viral hepatitis, ethanol consumption > 210 g/week and steatosis. All patients had serum samples collected for determination of ELF score on the same day of ultrasonography. The evaluation of ELF markers (hyaluronic acid, procollagen III and inhibitor of metalloproteinase 1) was performed by chemiluminescence (Siemens Healthcare Diagnostics).

Results: 78 patients were evaluated; 50 (64%) were female, mean age 50 ± 14 years. According to Niameye classification, patients were divided into three groups: 7 patients (9%) presented pattern A of fibrosis, 33 (42%) pattern C/D and 38 (49%) pattern E/F. Groups showed the following ELF scores, according to the pattern of fibrosis: A/B = 8.53 ± 0.40, C/D = 9.31 ± 1.23, E/F = 9.52 ± 0.93. Significant difference was observed between groups A/B and E/F (P < 0.01).

Conclusion: In patients with Schistosomiasis mansoni the ELF score was able to discriminate between patients with patterns A/B (absent or mild) of fibrosis (E/F) (advanced fibrosis). The test can be a useful tool for the diagnosis and for monitoring fibrosis progression in patients with Schistosomiasis mansoni in situations where ultrasound is not available.

Interferences by hemolysis, lipemia and bilirubin on routine parameters on chemistry analyzers in a pediatrics hospital

S. Agarwal, G. Vargas, G. Buffone, S. Devaaj. Texas Children’s Hospital and Baylor College of Medicine, Houston, TX

Background: Clinical laboratory assays can be affected by different interferences, most commonly, hemoglobin, lipids, bilirubin, auto-antibodies, and heterophile antibodies. Our goal was to study the effect of interference by hemolysis, lipemia and bilirubin on routinely performed parameters on various chemistry analyzers including VITROS 5600, BN Prospect, Dimension Xpand, Architect i1000SR, and Advia Centaur using pediatric samples in the Texas Children’s Hospital laboratory. Further we wanted to establish cut-off indices above which these interferences confound analysis of pediatric samples. Methods: We tested the effect of hemolysis on K+, AST, LDH, TBL, ALT, CK, Mg++, ALKP, ALKP, Fe, Lipase,NH3+ and phosphorus on VITROS 5600. Similarly for lipemia interference we analyzed HIV-1,2,Testosterone, Progesterone, Ceruloplasmin,Haptoglobin,C3 / C4, IgG / IgM / IgA, Vitamin D,AFP,AlbHBC,HCG,CK-MB,TSH,Albumin,Ferritin and Glucose. Lastly, for icteric interference we performed analyses for Estradiol, Folate, ALKP, ALT, GGT, Glucose, Na+, Cortisol, C4, Haptoglobin and HbA1c on the respective analyzers. Experiments were carried out with test samples from 3 different serum pools spiked with increasing concentrations of hemolysate (0.75g/l, 1.5g/l, 3.0g/l, 6.0g/l), 20% Intralipid (400mg/dl, 1000mg/dl, 2000mg/dl) and commercially available Bilirubin (100mM, 250mM and 500mM). These were then analysed on the various instruments in laboratory: VITROS 5600, Architect i1000SR, Prospect, Xpand, and Centaur. The Hamblin’s (H), Lipemia-(T) and Icterus- (I) indices were measured and documented on VITROS 5600. Lastly, for lipemic interference (>2000mg/dl) we further treated the samples with Lipoclear (1:5 ratio) and then re-analyzed the samples.

Results: We categorized hemolysis by H-index of 101-250 as mild, 251-500 as moderate, 501-999 as significant and H-index of >1000 as grossly hemolysed. Similarly, for Lipemia T-index of < 100 was considered mild,100-250 as moderate and T-index of >250 as severely lipemic. For icteric evaluation I-index of 0-5 was characterized as normal, 5.1-9.9 as mild, 10.0-19.9 as moderate and ≥ 20 as grossly icteric. For significant hemolysis, the main parameters affected, and which shouldn’t be reported included AST, LDH, TBL, and NH3+. All the measured analytes were compromised by gross hemolysis and these samples should be rejected. None of the analyzed parameters were significantly affected by the level of Icterus. With regards to lipemia, mild lipemia (<400mg/dl) did not affect the assays while Ceruloplasmin, Haptoglobin, C3, C4, and Immunoglobulins (IgG, IgA, IgM) were significantly affected by moderate (400-1000 mg/dl) and severe lipemia (>2000 mg/dl), and hence shouldn’t be reported. Vitamin D also showed a significant decrease in lipemic samples (decrease of 10-15%). However, since most samples are drawn in a postprandial state, we tested the effect of Lipoclear. Addition of Lipoclear to moderately lipemic samples significantly attenuated the effect of lipemia interference on the above mentioned analytes.

Serum Neopterin Levels in Patients with Pulmonary Embolism

S. Abusulay, F. Akyurek, A. Unlu, Z. Bayakterzi, E. Kurtipek. Selcuk University Faculty of Medicine, Konya, Turkey; 2Meram Training and Education Hospital, Konya, Turkey

Background: Neopterin (D-erythro-1-2-3-trihydroxypropylpterin) is produced from guanosine triphosphate by activated human monocytes, monocyte derived dendritic cells, and macrophages. Release and production of neopterin is stimulated mainly by interferon-γ (IFN-γ) released by activated Th1- lymphocytes during the cellular immune response. Pulmonary thromboembolism (PTE), is an extremely common medical problem. Yet despite its frequency, much remains to be learned regarding the pathogenic mechanisms that initiate pulmonary thromboembolism. Marked activation of endothelium, platelets, and leukocytes are key events in thrombogenesis in pulmonary thromboembolism. The role of clinical laboratories is to give accurate, fast and reliable results to clinicians. Also, early detection of diseases as pulmonary thromboembolism is important to take care before the serious complications. The aim of this study was to determine serum neopterin concentrations as an early biomarker on patients with pulmonary thromboembolism.

Methods: Blood samples were collected from 41 healthy control and 38 patients with pulmonary embolism. Patients with chronic disease and inflammatory disorders were excluded. This study was approved by local ethic committee. Serum neopterin levels were analyzed with fluorometric detection by high performance liquid chromatography. Briefly, 100 μL trichloroacetic acid was added to 500 μL serum sample, vortexed and centrifuged at 10000 g for 10 minutes. Supernatant was injected to C18 chromatographic column on Agilent HPLC system. Chromatographic detection was performed at 353 and 438 nm excitation and emission wavelength. This method’s coefficient of variation and 1% bias values were 4.21±3.50; 6.89±5.62 and 8.14±6.64 for 0.5, 5 and 10 μmol/L, respectively. Statistical analysis was performed with SPSS v16.

Results: Serum neopterin levels were significantly lower in control group (5.72±2.29 μmol/L) compared to patient group (7.83±4.45 μmol/L) (p=0.049) according to Mann-Whitney U test.

Conclusions: Activated T cells and macrophages synthesise and release a number of cytokines whose main function is immunoregulation. As a marker of cellular immune response activation depending on IFN-γ release, neopterin may better reflect the disease. Our findings suggest that neopterin levels may be used as an immunological marker in follow-up the disease.

How non-standardized serum creatinine-based definitions of acute kidney injury contribute to disparate reported incidence rates of contrast-induced nephropathy

J. S. McDonald, R. J. McDonald, E. E. Williamson, D. F. Kallmes. Mayo Clinic, Rochester, MN

Background: Prior controlled studies of intravascular contrast-induced nephropathy (CIN), acute kidney injury (AKI) resulting from iodinated contrast material administration, have reported incidence rates ranging from 2% to 40%. This discrepancy may be partially explained by the lack of a standardized serum creatinine (SCr)-based definition of AKI. To date, there is little evidence regarding how different definitions of SCr-defined AKI and baseline renal function affect the incidence of AKI, and which, if any, of these definitions provide a reliable means to distinguish between CIN and contrast-independent AKI. In the current study, we examined how using different SCr definitions of AKI and baseline renal function affect AKI incidence rates in a propensity score-matched cohort of contrast-enhanced and unenhanced CT scan recipients.

Methods: Contrast-enhanced and unenhanced abdominal, pelvic, and thoracic CT scans performed at our institution from 2000-2010 and accompanying pre- and post-scan SCr results were identified. Contrast and noncontrast scan recipients of similar clinical and demographic characteristics were compared following propensity score-based 1:1 matching. AKI was defined using absolute (SCr ≥ 0.5mg/dl and ≥ 0.3mg/dl over baseline), relative (SCr ≥ 25% and ≥ 50% over baseline), and hybrid definitions (SCr ≥ 0.5mg/dl or ≥ 25%, or ≥ 0.3mg/dl or ≥ 50% over baseline). Baseline renal function was defined by using either the mean SCr result 24 hours or 7 days prior to scan. The incidence of AKI was compared between groups using Fisher’s exact test.

Results: Following 1:1 matching, 21,372 patients were identified who underwent a contrast enhanced (N=10,636) or unenhanced CT scan (N=10,636). Using the six definitions of AKI, the incidence of contrast-dependent AKI ranged from 2% to 15% while the incidence of contrast-independent AKI ranged from 1% to 14%. Regardless of AKI definition, the rates of contrast-independent AKI were statistically similar to the rates of contrast-dependent AKI (ORs ranged from 0.91 (95% CI 0.66-1.24), p= 0.85 to 1.84 (91.3-3.75), p= 0.08). Higher incidences of AKI were observed if baseline renal function was defined using the mean 7-day pre-scan SCr result compared to using the mean 24-hour pre-scan SCr result.

Conclusion: Differing definitions of AKI and baseline renal function contribute to disparities in the reported incidence of AKI. However, no definition could extricate CIN from contrast-independent AKI causes in our cohort.

Intravenous Contrast Material Exposure is not an Independent Risk Factor for Dialysis or Mortality

J. S. McDonald, R. J. McDonald, E. E. Williamson, D. F. Kallmes. Mayo Clinic, Rochester, MN

Background – Contrast-induced nephropathy (CIN), defined as acute kidney injury (AKI) occurring immediately after exposure to iodinated contrast material, is generally reported to be a self-limited phenomenon. However, concern remains that CIN can cause irreversible nephrotoxicity resulting in dialysis and death, particularly in patients with specific pre-existing comorbidities including renal failure, diabetes mellitus, and congestive heart failure. In the current study, we sought to determine the true incidence of short-term dialysis and mortality following intravenous contrast administration among individuals with closely matched demographic and clinical characteristics using propensity score analysis.

Methods - All contrast-enhanced and unenhanced abdominal, pelvic, and thoracic CT scans performed at our institution from 2000-2010 and related pre- and post-scan serum creatinine (SCr) results were identified. Contrast and noncontrast scan recipients were compared following propensity score-based 1:1 matching to reduce intergroup selection bias. Patients with pre-existing diabetes, congestive heart failure, or chronic or acute renal failure were identified as high-risk patient subgroups for nephrotoxicity. The effects of contrast exposure on the incidence of AKI (SCr ≥ 0.5mg/dl above baseline within 24-72 hours of exposure), and dialysis or death within 30 days of exposure were determined using odds ratios and covariate-adjusted Cox-proportional hazard models.

Results - 1:1 propensity score matching yielded a cohort of 21,346 patients (10,673 contrast-enhanced exams/10,673 noncontrast exams). Within this cohort, the risk of AKI (OR=0.94 (95% CI: 0.83-1.07), p=0.38), emergent dialysis (OR=0.93 (0.52-1.65), p=0.89), and 30-day mortality (HR=0.97 (0.87-1.06), p=0.45) was not significantly different between contrast and noncontrast groups. Although patients who developed AKI had overall higher rates of dialysis and mortality, contrast exposure was not an independent risk factor for either outcome (dialysis: OR=0.89 (0.40-2.01), p=.78; mortality: HR=1.03 (0.82-1.32), p=.63). Similar findings were observed among the subgroups of patients with renal failure, diabetes, and congestive heart failure.

Conclusion - Intravenous contrast material administration was not associated with excess risk of AKI, dialysis, or death, even among patients with comorbidities reported to predispose them to nephrotoxicity.

Neutrophil gelatinase-associated lipocalin (NGAL) and Pentraxin-3 (PTX-3) Levels in Chronic Renal Failure and their relationship with Inflammation

O. Sarı, N. Eroğlu, S. Cigerli, B. Aslan, T. Basturk, M. Sevinç, A. Unsal, V. ışılı etalf trainig and research hospital, İstanbul, Turkey; Quality Management Program-Laboratory Services, Toronto, ON, Canada

Background: Early diagnosis of Chronic Renal Failure (CRF) provides to initiate the effective treatments that can decelerate the progress of the disease and improve prognosis. However, lack of early predictive biomarkers presents difficulties in early diagnosis. Therefore, finding biomarkers that considerably increases in the early stages of CRF and demonstrates correlation with the disease progress is necessary. NGAL is a known biomarker of acute kidney injury that is secreted in response to renal tubular epithelial cells damage. Increased NGAL levels are determined in the blood and urine following acute renal injury. Pentraxin-3 (PTX-3) is an inflammatory mediator. In contrast to other members of the pentraxin family such as CRP and...
Serum Amidol Protein, PTX-3 is produced in the inflammation site and shows close correlation with the level of tissue damage. Inflammation plays an important role in the progression of the CRF and contributes to increased mortality and morbidity observed in CRF.

In this study, we investigated serum NGAL and PTX-3 levels and their relationship with the severity of renal damage in patients with early stage CRF.

Method: 20 (2 male and 18 female) non diabetic Stage 1 and 34 (17 male and 17 female) Stage 2 CRF patients were included in this study. Average age in the Stage 1 CRF group was 42.55±7.00, and in the Stage 2 CRF group 47.44±7.47. In both groups, serum NGAL and PTX-3 were measured by using the ELISA method from Bioscience Human and Aviscera Bioscience, respectively.

Results: NGAL levels in patients with Stage 2 CRF were higher than that of the patients with Stage 1 CRF (p<0.01). ROC analysis and diagnostic tests used for the calculation of a diagnostic cut off value for Stage 2 CRF. For the diagnostic cut off value of 1037 pg/ml, sensitivity was 73.5%, specificity 70.0%, positive predictive value 80.65%, and negative predictive value 60.87%. Area under the curve was estimated as 73.3% and its standard error was 6.9%. In the patients with NGAL levels higher than 1073 pg/ml, the probability of having Stage 2 CRF was found to be 6841 times higher than that of the patients with NGAL levels less than 1037 pg/ml. In Stage 1 and 2 CRF groups, 19.4% and 80.6% of the patients had NGAL levels higher than 1037, respectively. In Stage 2 cases, there was a positive correlation between serum creatinin and NGAL concentrations (r=0.362; p=0.05). In Stage 1 and 2 CRF patient groups, CRP and PTX-3 concentrations did not show correlation with eGFR values. There was no statistically significant correlation between NGAL and PTX-3.

Conclusion: The serum NGAL concentrations were found to be higher in Stage 2 CRF than Stage1 CRF group. Our results indicate that NGAL could be used as a strong and independent diagnostic biomarker for the early stage CRF and a risk for disease progression. We did not observe statistically significant correlation between serum NGAL and PTX-3 levels.

---

**Prevalence of metabolic syndrome among hypertensives in Ghana**

C. NKRUMAH1, W. OWIREDU2. 1METHODOIST HOSPITAL, WENCHI, Ghana, 2KWAME NKRUMAH UNIVERSITY OF SCIENCE AND TECHNOLOGY, KUMASI, Ghana

**Background:** Metabolic syndrome can be found in approximately one-third of patients who do not have diabetes but have hypertension. There are numerous correlations between the metabolic syndrome and hypertension, although this is not always the case. As metabolic syndrome and hypertension are independent risk factors for the same disease process, namely cardiovascular disease, it is possible that patients suffering from both these disease entities may have a compounded risk. Our study will therefore attempt to determine the prevalence of metabolic syndrome and investigate the proposed association between these two disease entities.

**Methods:** This cross-sectional study was conducted at the Hypertension Clinic of the Department of Medicine, Komfo Anokye Teaching Hospital (KATH), Kumasi, Ghana between April 2009 and November 2010. Informed consent was obtained from 300 participants consisting of 200 hypertensives (diagnosed by a Consultant Physician based on WHO – International Society of Hypertension Guideline of blood pressure ≥140/90 mmHg or use of antihypertensive) and 100 apparently healthy normotensives served as control. Blood samples were collected in the morning after an overnight fast of at least 12 hours. Serum and plasma were stored at -80°C after centrifugation at 2000g for 5 minutes until assayed. Fasting blood glucose (FBG), Apolipoprotein A1 (Apo A-1), Apolipoprotein B (Apo B), Total Cholesterol (TC), Triglyceride (TG) and High Density Lipoprotein (HDL) were measured on an Auto-Analyzer (Flexor junior, Vital Scientific N.V., The Netherlands).

**Results:** The prevalence of MetS among the hypertensive patients were significantly higher than the normotensive control (56.5% vs 9.0%, 54.5% vs 5.0% and 65.5% vs 15.0%, p<0.001) using NCEP ATP III, WHO and IDF criteria respectively. Irrespective of the criteria applied, all the components of MetS were significantly higher among the hypertensive patients as compared to the normotensive control. Among the hypertensive patients, the highest prevalence of cardiovascular risk factor was abdominal obesity as measured by WHR (77.0%), followed by reduced HDL cholesterol (74.0%). From the univariate analysis, females were at about 3 times at risk of developing hypertension as compared to the male counterpart (OR = 2.7; 95% CI = 1.6-4.4; p = 0.0000). Reduced apolipoprotein A1 served as a risk factor (aOR = 13.4; 95% CI = 1.5-121.4; p = 0.0210) whilst high apolipoprotein A1 protects the individual from developing hypertension (aOR = 0.1; 95% CI = 0.0-0.2; p = 0.0000). High apolipoprotein B poses about 9 times risk of developing hypertension as compared to the normal level (aOR = 9.3; 95% CI = 4.2-20.9; p = 0.0000). Both Impaired fasting glucose and diabetes each pose more than 10 times risk of developing hypertension as compared to normoglycemia.

**Conclusion:** The study demonstrated that, hypertension is more than just elevated blood pressure in our setting; it is intimately associated with the metabolic syndrome. There is therefore the need for metabolic screening of all hypertensives and increased awareness on the critical importance of public health strategies aimed at reducing risk factors in the entire population. Early detection and treatment of the global risk profile should thus become a priority.

CEDIA® Mycophenolic Acid Applications on the Beckman Coulter AU480, AU680 and AU5800 Analyzers

D. L. Cheng, C. Wong. Thermo Fisher Scientific, Fremont, CA

Background: Mycophenolic Acid (MPA) is metabolized from Mycophenolate Mofetil (MMF) or Mycophenolate Sodium. It is an immunosuppressant used in the prevention of tissue rejection for patients who have undergone renal and heart transplants. MPA is a specific inhibitor of inosine monophosphate dehydrogenase (IMPDH) - an enzyme used by B and T lymphocytes for de novo purine synthesis. This repression of B and T cell proliferation results in the desired immunosuppressive effects.

Methods: The CEDIA MPA Assay is based on the enzyme β-galactosidase, which has been genetically engineered into two inactive fragments. MPA in the human plasma sample competes with MPA conjugated to one inactive fragment for antibody binding site. Once MPA in the sample binds to antibody, inactive enzyme fragments reassociate to form active enzymes. The amount of active enzymes results in an absorbance change that is directly proportional to the amount of MPA in the patient sample. This change is measured spectrophotometrically for a quantitative value of concentration. The Beckman Coulter AU480/AU680/AU5800 analyzers are new applications for the CEDIA MPA Assay. Analyzer performance was determined for precision, linearity, limit of detection, and accuracy on the Beckman Coulter AU480/AU680/AU5800 clinical chemistry analyzers, over the range of the assay (0.30 μg/mL). Results were measured against the reference analyzer Hitachi 917.

Results: All studies were evaluated using CLSI guidelines. Three levels of MPA controls were used in the studies. The precision ranged from 6.1-2.2%CV for within-run and 7.7-2.5%CV for total run. Linearity was measured and confirmed over a range of 1.8-11.9 μg/mL. The limit of detection on the AU480/AU680/AU5800 yielded 0.07 μg/mL. Accuracy was measured using patient correlation against the reference analyzer Hitachi 917, which yielded a Deming’s Regression for each analyzer: AU480 = 0.992x(Hitachi 917) - 0.096 (N = 107, r = 0.998), AU680 = 0.985x(Hitachi 917) - 0.043 (N = 107, r = 0.998), AU5800 = 0.993x(Hitachi 917) - 0.089 (N = 107, r = 0.998).

Conclusion: All measured studies demonstrated acceptable performance, validating the use of the CEDIA MPA Assay on the Beckman Coulter AU480/AU680/AU5800 analyzers, and will provide an effective monitoring system for patients receiving MMF or Mycophenolate Sodium therapy.

Fructosamine and Glycated albumin with Risk of Coronary Heart Disease and Death

E. Selvin1, A. M. Rawlings1, P. Lutsey2, J. Pankow2, L. Kao1, M. Steffes2

Background: HbA1c is the standard measure to monitor glucose control and is now used for diagnosis of diabetes. Fructosamine and glycated albumin are markers of short-term glycemic control that may add complementary information to HbA1c. However, the associations of fructosamine and glycated albumin with cardiovascular outcomes are uncharacterized.

Methods: measured glycated albumin and fructosamine in 11104 adult participants (792 with a history of diabetes) of the community-based ARIC Study without a history of diabetes. Fructosamine and glycated albumin were signiﬁcantly associated with coronary heart disease and total mortality. We compared these associations to those for HbA1c.

Results: Baseline HbA1c was highly correlated with fructosamine (Pearson’s r = 0.82) and glycated albumin (Pearson’s r = 0.86). During over two decades of follow-up there were 1,032 new cases of coronary heart disease and 2,594 deaths. In Cox proportional hazards models adjusted for traditional cardiovascular risk factors, elevated baseline levels of fructosamine and glycated albumin were signiﬁcantly associated with coronary heart disease and total mortality (Figure). After additional adjustment for HbA1c, the associations were attenuated but remained signiﬁcant, particularly at diabetic levels of fructosamine and glycated albumin. The associations with death were J-shaped, with an elevation of risk also apparent at the lowest levels of each biomarker, as has been previously observed for HbA1c.

Conclusion: The acceptance of new measures of hyperglycemia is partly dependent on establishing their association with long-term outcomes. We found that fructosamine and glycated albumin were associated with coronary heart disease and mortality and that these associations were similar to those observed for HbA1c. The elevated risk of death at very low levels of fructosamine, glycated albumin, and HbA1c deserves further examination.

A-140

Study of the Association between Endothelial Nitric Oxide Synthase G894T Gene Polymorphism and Heart Failure Severity

d. I. hashad, S. Marzouk, M. sadaka, R. Zaghloul. FACULTY OF MEDICINE, Alexandria, Egypt

Objectives: The aim of the study was to investigate the association between endothelial nitric oxide synthase (eNOS) G894T gene polymorphism and severity of congestive heart failure (CHF) in a group of Egyptian patients.

Methods: This study was conducted on 30 consecutively selected Egyptian patients admitted to the Cardiology department at Alexandria Main University Hospital suffering from non valvular CHF which was documented clinically and by ECG. Thirty age & sex matched healthy individuals were also included in the study as a control group. eNOS G894T gene polymorphism was studied using polymerase chain reaction-Restriction fragment length polymorphism (PCR-RFLP).

Results: Genotype distribution of eNOS G894T gene polymorphism among patients revealed 13 (43.3%) patients of GG genotype (wild type), 11 (36.7%) of GT genotype (heterozygote) and 6 (20%) of the TT genotype (homozygote for the mutant allele). Among the controls, 16 (53.3%) were GG genotype, 12 (40%) were GT genotype and 2 (6.7%) were TT genotype. Thus, no statistically significant difference in genotype distribution between patients and controls was observed. In addition, the present study showed no statistically significant difference between different eNOS patients’ genotypes as regards NYHA classes, ejection fraction and six-minute walk test. The prevalence of TT genotype was significantly higher in ischemic cardiomyopathy patients when compared to those who had dilated cardiomyopathy and also in hypertensive patients as compared to normotensive patients.

Conclusions: Although the mutant eNOS G894T allele is associated with both hypertension and dilated cardiomyopathy in Egyptian heart failure patients, it was not correlated to disease occurrence or severity.

A-141

Seasonal Variation of Vitamin D Deficiency in a Large Rural Health System: Effect of Age and Sex on Deficiency Prevalence

25 hydroxy Vitamin D (25OH Vit D) continues to be a commonly ordered test to assess bone health in the large, rural Geisinger Health System outpatient population in central Pennsylvania USA (latitude 40-41 degrees N). It is well known that seasonal variation of 25OH Vit D levels exists in temperate latitudes as sunlight exposure varies. Our objective is to report practical impact of monthly surveillance of 25OH Vit D seasonal deficiency/sufficiency prevalence during 2009 to 2013 (N=228,714) using clinical cutoffs of <20, 20-30, and 30-100 ng/mL to judge Deficiency, Insufficiency, and Sufficiency, respectively.

Monthly test volumes increased dramatically in 2009 when the test was first performed in house (2300/month in July 2009 to 4000/month in Jan 2010). Since then the volume has steadily increased to 5500/month. Our osteoporosis management program reports that patients are uniformly monitored with 25OH Vit D and are at

CLINICAL CHEMISTRY, Vol. 60, No. 10, Supplement, 2014 S37
steady state as far as population enrollment stands. Steady increases of 25OH Vit D test volumes (approximately 15%/year) may be attributed to generally increasing numbers of outpatients rather than significant changes in utilization.

Over the course of July 2009 to December 2013, cyclical seasonal variation was documented by monthly prevalence plots, with deficiency rates lowest in July-August-September (16.5%) and highest in Jan-Feb-March (27.7%). Inversely, sufficiency rates were highest in Jul-Aug-Sept (48.5%) and lowest in Jan-Feb-Mar (40.5%). Because deficiency rates repeatedly increase from summer to winter by an average of 68%, it is important to advise clinicians to interpret 25OH Vit D levels and prescribe supplementation taking the month of the year into account. Although common practice is to supplement 25OH Vit D in patients with deficient or insufficient levels (i.e. < 30 ng/mL), a systematic study of prescribing patterns has not yet been undertaken.

In November 2012, the 25OH Vit D immunoassay was changed from Diasorin to Roche. Correlation between the two assays using patient specimens (N=152) was acceptable; Deming slope = 0.963; correlation coefficient = 0.8455. Ongoing monthly deficiency prevalence, although similar in amplitude and periodicity, changed somewhat with Roche Jan-Feb-Mar 2013 deficiency prevalence trending 11% higher and Roche Jul-Aug-Sept 2013 deficiency prevalence trending 24% lower than prior comparable monthly Diasorin results. It is too early to tell if this difference is physiological, analytical, or coincidental. Although the population surveillance data are uncorrected by patient clinical status, the assay change per se may have an effect on shifting population outcome data, and should be more extensively studied along with more traditional specimen correlation.

We conclude that seasonal variation of 25OH Vit D significantly affects deficiency prevalence and has the potential to change treatment on a population basis. The season of testing should be factored into treatment and other clinical considerations based on limited duration cross-sectional studies. Additional studies are needed to determine if different assays perform differently in populations exposed to different amounts of sunlight and if these differences may be due to levels of Vit D precursor or binding protein.

**Evaluation of circulating levels of inflammatory and bone formation markers in Axial Spondyloarthritides**

**Background:** Studies have demonstrated the important role of bone remodelling and osteoimmunology in the progression of inflammatory lesions in Axial Spondyloarthritis (SPA) disease.

**Objective:** This study was conducted to evaluate the inflammatory response by analysis of the serum levels of pro-inflammatory and new bone formation markers in patients with SPA who were treated or not treated with anti-tumor necrosis factor alpha (anti-TNF-α) or anti-steroidal drugs (NSAIDs) and to correlate these markers with the clinical evaluation scores of the disease activity.

**Methodology:** The serum levels of myeloperoxidase (MPO), adenosine deaminase (ADA), nitric oxide metabolites (NOs), bone alkaline phosphatase (BAP), Dickkopf-1 (DKK-1), and osteoprotegerin (OP) were measured in 52 SPA patients who were treated or not with anti-TNF-α or NSAIDs and in 26 healthy controls using colourimetric and enzyme immunoassays. The activity and the severity of illness in patients with SPA were assessed using questionnaires (BASMI, Bath Ankylosing Spondylitis Metrology Index; BASFI, Bath Ankylosing Spondylitis Functional Index; and BASDAI, Bath Ankylosing Spondylitis Disease Activity Index). The data were expressed as the mean ± standard deviation of the mean (SD) for symmetric distribution or in percentage. Comparison of clinical parameters and bone biomarkers between all groups were done with analysis of variance (ANOVA) followed by Bonferroni post hoc test for multiple comparisons among the groups. P < 0.05 was considered to be statistically significant. Results: A significant difference between the controls and the patients without medication was observed in relation to NOs, BAP, and OP (p < 0.01). When the patients were compared with regard to their treatment, there were no clinically significant differences between the groups (p > 0.05).

**Conclusion:** The NOs, BAP, and OP are emerging as an important inflammatory pathway in Axial Spondyloarthritis. Also the anti-TNF-α or non-steroidal drugs reduce the inflammation and destruction, however these treatment does not modify the serum levels of these biomarkers.

### A-143

**Suspected Lassa Fever (LF) Case Outcomes: A Comparison to a Non-Febrile Population in Sierra Leone**

B. L. Brown,1 M. L. Boisen,1 L. M. Moses,2 J. S. Schieffelin2, A. Goba,1 M. Momoh1, M. Fullah1, F. K. Kamara1, L. Kanneh1, S. H. Khan1, D. Oottamasathien3, D. S. Grant2, D. Beckham5, K. R. Pitts1, J. Barnett4, R. F. Garry4,1. *Corgenix, Inc., Broomfield, CO, 2Tulane University, New Orleans, LA, 3Kenema Government Hospital, Kenema, Sierra Leone, 4Ministry of Health and Sanitation, Kenema, Sierra Leone, 5University of Colorado Anschutz Medical Campus, Denver, CO*

**Background:** Lassa virus (LASV) is the causative agent for Lassa fever (LF), causing an estimated 100,000 - 300,000 cases annually. The precise factors resulting in fatal outcome in LF patients are still largely uncharacterized, although hypovolemic shock is thought to ultimately result in death of afflicted subjects. Additionally, signs of acute renal failure are consistently noted preceding fatal outcomes. Evaluating the difference in clinical and laboratory outcomes between LF cases and non-febrile controls is important to better characterize the clinical presentation of patients with LASV infection and potentially select patients with a higher pre-test probability of infection for diagnostic testing.

**Methods:** This is a case controlled study of patients suspected of LASV infection, identified in Sierra Leone, West Africa. Cases include both suspected and confirmed LF patients who had a temperature of ≥38°C for ≥3 weeks and displayed clinical signs and symptoms of a LASV infection upon examination. Controls include non-febrile Sierra Leoneans with a temperature of <37.5°C. We measured five outcomes and compared results between the confirmed LF case group (n = 57) and the non-febrile control group (n = 118). We measured BMI, Pulse, BUN, Cr, and BUN:Cr ratio and correlation of clinical parameters with diagnosis and other clinical parameters. Other outcomes such as the metabolic panel and hemoglobin were collected and evaluated as well.

**Results:** Using the Wilcoxon-Mann-Whitney nonparametric test, we found that confirmed LF cases exhibit elevated BUN (p<0.0001) and Cr (p=0.0002) measurements (BUN: 10.5 mM/L, Cr: 216.3 μM/L) compared to non-febrile controls (BUN: 3.4 mM/L, Cr: 84.6 μM/L). Confirmed LF cases also had a significantly higher respiratory rate (p<0.0001) than the non-febrile controls (39.6 breaths per minute versus 21.6).

**Conclusion:** Early evaluation of BUN, Cr, and respiratory rate in febrile patients may aid in selecting patient populations at high risk for LF and improve diagnostic accuracy.

### A-144

**A comparative study of the prevalence of Salmonella typhi infection in the wenchi municipality using the Widal and culture methods**

C. NKRUNMAH1, M. AMOAH1. 1METHODIST HOSPITAL, WENCHI, Ghana, 2COLLEGE OF HEALTH, KINTAMPO, Ghana

**Background:** Salmonella typhi is a Gram negative bacterium that can cause typhoid fever. Worldwide, typhoid fever is a serious public health problem, with an estimated 22 million cases, resulting in 200,000 deaths. The burden of the disease lies mainly in developing countries including Ghana where the provision of sanitary conditions may be inadequate. However, not much research work has been done to explore the problem confronting citizens and ways to eliminate them. Yearly report from Methodist Hospital’s Laboratory, Wenchi (2012), indicates that 45.8% and 47.5% of In-patients and Out-patients respectively reacted to the Widal test. The total percentage of reactive cases in 2012 was 47.1%. This study was then carried out to determine the prevalence of typhoid fever and propose recommendations on the appropriate way of diagnosing the disease in Wenchi municipality.

**Methods:** Non-interventional exploratory study using a purposive sampling for the selection of respondents in March and April 2013. The study comprised 100 participants who were suspected of having typhoid fever and referred to the laboratory for diagnosis. Informed consent was obtained from each participant and then blood and stool specimens were collected. The blood was centrifuged and Salmonella
typhi H and O antibody titre determined following serial dilution with the Widal kits (Salmonella typhi Antigens H and O). After emulsification with physiological saline, the stool samples were then cultured directly onto Desoxycholate Citrate Agar (DCA). The plates were then incubated at 37 °C in for 24 hours and observed for bacterial growth. Culture results were then compared with the Widal test for each participant.

**Results:** About 41% of participants had high antibody titre to S. typhi H antigen while 12% also reacted to S. typhi O. The majority of the respondents were female (61%) and had the lowest reaction to the Widal Salmonella typhi H (42.6%) and O (11.5%) test but with no bacterial growth on the agar. The males (29%) had the highest reaction to the Widal Salmonella typhi H (51.7%) and O (17.2%) test and also with no bacterial growth on the agar. Irrespective of the antibody titre shown in the Widal test, there was no corresponding bacterial growth by culture.

**Conclusion:** The high antibody titres recorded by the Widal technique with no corresponding bacterial growth by culture may point to the existence of circulating antibodies established during previous exposure. Therefore relying solely on the Widal test may lead to over diagnosis of the infection and concomitant abuse of antibiotics which may contribute the emergence of resistant strains in our region. Proper diagnosis of Salmonella typhi should thus be based on bacteria culture and sensitivity testing.

**Performance of REBA MTB-XDR to detect Extensively Drug-resistant Tuberculosis in a High burden country**

1Division of Pulmonary and Critical Care Medicine, Busan Paik Hospital Inje University College of Medicine, Busan, Korea, Republic of; 2YD R&D Center, YD Diagnostics, Yongin-si, Gyeonggi-do, South Korea, Republic of; 3Department of Internal Medicine, Asan Medical School of Medicine, Asan Paik Hospital, Goyang, Gyeonggi-do, Korea, Republic of; 4Department of Pulmonary and Critical Care Medicine, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic of

**Setting:** Multidrug-resistant/extensively drug-resistant tuberculosis (MDR/XDR-TB) is a serious problem worldwide. The early diagnosis and treatment of MDR/XDR-TB is very important. The REBA-MTB-XDR (REBA-XDR) line probe assay has been developed recently for the detection of resistance to ofloxacin, kanamycin, and streptomycin in Korea.

**Objective:** The aim of this study was to evaluate the diagnostic accuracy of the REBA-XDR in detecting XDR-TB in acid fast bacilli (AFB) smear-positive sputum specimens.

**Design:** We prospectively enrolled 104 patients with AFB smear-positive specimens between July 2010 and January 2013. Mycobacterium tuberculosis was cultured in all samples. The performance characteristics were compared between the REBA-XDR and the conventional drug susceptibility test (DST), GenoType MTBDRsl assay, and DNA sequencing analysis results. The conventional DST results were considered to be the gold standard.

**Results:** Among the 104 specimens, MDR-TB was found in 29.8% (31/104) and XDR-TB in 7.7% (8/104). The sensitivity of the REBA-XDR in detecting resistance to ofloxacin, kanamycin, and streptomycin was 66.7%, 90.9%, and 60.0%, and the specificity was 93.3%, 93.5%, and 85.4%, respectively. The positive predictive values were 62.5%, 62.5%, and 40.9%, and the negative predictive values were 94.3%, 98.9%, and 92.7%, respectively. The accuracy was 89.4%, 93.3%, and 81.7%, respectively. Discordant results between REBA-XDR and conventional DST were found for ofloxacin in 11 samples (10.6%), for kanamycin in 7 samples (6.7%), and for streptomycin in 19 samples (18.3%). Two of 10 (20%) discordant REBA-XDR results for ofloxacin resistance and all 6 (100%) discordant specimens for kanamycin resistance corresponded to the results of the gold standard DNA sequencing test. Five of 10 (50%) discordant results for ofloxacin resistance and 2 of 6 (33.3%) discordant results for kanamycin in the MTBDRsl test corresponded to the results of the DNA sequencing test.

**Conclusion:** REBA-XDR seems to be a useful kit to “rule in” XDR-TB in a high-risk group for drug resistance, especially for the detection of kanamycin resistance.

**Circulating Presepsin (Soluble CD14 Subtype) in Patients with Severe Sepsis and Septic Shock: Data from the Albumin Italian Outcome SepsiS (ALBIOS) Study**

1IRCCS - Istituto di Ricerche Farmacologiche Mario Negri, Milano, Italy; 2Fondazione IRCCS Ca’ Granda - Ospedale Maggiore Policlinico, Università degli Studi di Milano, Milano, Italy; 3Fondazione Mario Negri Sud, Santa Maria Imbaro, Italy; 4A.O. San Paolo - Polo Universitario, Milano, Italy; 5Ospedale del Mugello, Borgo San Lorenzo, Italy; 6Ospedale San Giovanni di Dio, Orbetello Scarl, Italy

**Background:** The cornerstone of the emergency treatment of severe sepsis and septic shock is an early, goal-directed therapy. Presepsin, a soluble fragment of CD14 that participates in the innate recognition of pathogens, has been proposed as a novel diagnostic and prognostic marker in sepsis.

**Aims:** To validate presepsin as a prognostic marker in a representative cohort of septic patients.

**Methods:** Blood samples were collected 1, 2 and 7 days after enrolment in 997 patients with severe sepsis or septic shock enrolled in the multicenter Albumin Italian Outcome SepsiS (ALBIOS) trial (NCT00707122). Presepsin was measured in a central laboratory with a chemiluminescent enzyme immunoassay (PATHFAST Presepin, Mitsubishi Chemical). The relation between presepsin concentration and mortality in Intensive Care Units (ICU) or at 90 days was assessed with Cox proportional hazards multivariable models. Prognostic discrimination was tested with reclassification metrics.

**Results:** Concentration of presepsin on day 1 was 946 [492-1887] ng/L (median [Q1-Q3]) and increased gradually with the number of organ dysfunctions and the number of newly developed organ failures in ICU. Circulating presepsin rose in decedents over 7 days in ICU while it markedly decreased in survivors (p<0.0001 for time-survival interaction). Presepsin on day 1 independently predicted ICU and 90-day mortality (Figure). Addition of presepsin measured on day 1 on top of all risk factors significantly improved prognostic discrimination and correctly reclassified the risk of 90-day mortality (c-statistics from 0.77 to 0.79, p<0.004; integrated discrimination improvement IDI = 0.03 [0.02-0.04], p=0.0001; continuous net reclassification index NRI = 0.53 [0.40-0.65], p<0.0001).

**Conclusion:** Presepsin is a robust predictor of mortality in patients with severe sepsis and septic shock. It provides incremental information on top of widespread clinical risk factors and may help in early risk stratification.

**Neutrophil-Gelatinase -Lipocalin in adult cardiac surgery patients: beyond AKI**

C. Cosma1, M. Zaninotto1, R. Bianco2, M. Kosovici2, G. Gerosa2, M. Plebani1.

1Department of Laboratory Medicine, University-Hospital, Pudova, Italy; 2Division of Cardiac Surgery, Department of Cardiac, Thoracic and Vascular Sciences, University, Padova, Italy

**Background:** Neutrophil-gelatinase-associated lipocalin (NGAL) has been largely described as an early marker of acute kidney injury. We report the association of urinary NGAL (uNGAL) values with different adverse outcomes in adult cardiac surgery patients, particularly the need for continuous venous hemofiltration (CVVH), cardiac mechanical assist devices and low cardiac output syndrome.

**Clinical Studies/Outcomes**

**Tuesday, July 29, 9:30 am – 5:00 pm**

**CLINICAL CHEMISTRY, Vol. 60, No. 10, Supplement, 2014**

S39
Materials and methods: fresh urine sample of 137 patients (34 females and 103 males; mean of age 64 y) undergoing cardiac surgery (coronary artery bypass, artificial heart valve, heart transplants, complex cardiac surgery) have been collected before, immediately after surgery and then 24 h and 48 h after. AKI was defined as an increase in plasma creatinine levels (more than 50% or more than 0.3 mg/dL (26.5 umol/L) in comparison to the preoperative value during the first 48 h after surgery. uNGAL has been evaluated using a chemiluminescent microparticle immunoassay (CMIA, Architect, Abbott Diagnostic) showing during the study a total imprecision (CV) ranging from 3.85 to 2.35% (20 ug/L and 1218 ug/L, respectively). The reference ranges adopted are 2-120 ug/L for uNGAL and 53-97 (females), 62-115 umol/L (males) for plasma creatinine, respectively.

Results: Mean uNGAL levels peaked immediately after cardiac surgery (630 ± 890 (SD) ug/L) and remained significantly higher 24 and 48 hours after surgery (565 ±842 and 293±364, respectively, p<0.0003). 24 patients (17%) developed AKI (mean of basal creatinine values and 48 hours after cardiac surgery 106±30.9 and 346.5±127.57 respectively, p<0.001).

Accuracy of uNGAL (AUC) as a predictor for AKI immediately after cardiac surgery and 24 and 48 hours later was 0.775 (95% confidence interval [CI], 0.660 to 0.890), 0.864 (95% CI, 0.788 to 0.940) and 0.838 (95% CI, 0.749 to 0.926), respectively. uNGAL levels correlated significantly with the need of CVVH, cardiac mechanical assist devices and low cardiac output syndrome being AUC 0.862 (95% CI, 0.779 to 0.945), 0.913 (95% CI, 0.840 to 0.986) and 0.910 (95% CI, 0.840 to 0.981), respectively.

Conclusions: Our study confirms the clinical usefulness of NGAL measurement for the early diagnosis of AKI but underlines that relevant clinical informations on adverse outcome of patients undergoing cardiac surgery may also be obtained.

**Background:** Persons with pre-diabetes and diabetes are at high risk for cardiovascular events. However, the relationships of pre-diabetes and diabetes to development of subclinical myocardial damage are unclear. Our objective was to characterize the associations of pre-diabetes, undiagnosed diabetes, and diagnosed diabetes with 6-year incidence of subclinical myocardial injury, as assessed by a novel highly sensitive assay for cardiac troponin T (hs-cTnT).

**Methods:** We measured hs-cTnT at two time points, 6 years apart, among 8692 participants of the community-based Atherosclerosis Risk in Communities (ARIC) Study without a history of heart disease, silent MI by ECG, or stroke at baseline (1990-92). The primary outcome was incidence of elevated hs-cTnT (≥14 ng/L) at 6 years of follow-up.

**Results:** Cumulative probabilities of elevated hs-cTnT (≥14 ng/L) at 6 years among persons with no diabetes, pre-diabetes (HbA1c 5.7-6.4%), undiagnosed diabetes (HbA1c ≥6.5%), and diagnosed diabetes were 4.1%, 7.6%, 10.2%, and 16.9%, respectively. Across these same categories and compared to persons with no diabetes and HbA1c <5.7% (reference), the adjusted relative risks for incident elevated hs-cTnT were 1.40 (95%CI 1.13, 1.73), 1.85 (95%CI 1.24, 2.75), and 2.85 (95%CI 2.14, 3.75).

**Conclusion:** Pre-diabetes and diabetes were strongly associated with the future development of elevations in troponin T far below the threshold for a diagnosis of myocardial infarction. The results from this community-based prospective study provide evidence for a deleterious effect of hyperglycemia on the myocardium, possibly reflecting a microvascular etiology. Our findings underscore the importance preventing progression to early hyperglycemic states and development of diabetes.
Almost all patients (93%) had higher levels of urinary NGAL than the higher value of the controls; the respective frequency for the other markers was: 68% for serum NGAL and serum Cys-C, 50% for urinary Cys-C and only 10% for urinary KIM-1. All studied markers correlated with eGFR: serum Cys-C (r = -0.758, p < 0.001), serum NGAL (r = -0.627, p < 0.001), urinary Cys-C (r = -0.498, p = 0.008), urinary NGAL (r = -0.430, p = 0.01) and urinary KIM-1 (r = -0.369, p = 0.021). Only serum Cys-C strongly correlated with the involved serum free light chain (r = 0.806, p < 0.001). Urinary NGAL correlated also with urinary Cys-C (r = -0.880, p < 0.001), serum NGAL (r = 0.503, p = 0.002), 24-h proteinuria (r = 0.431, p = 0.01) and ISS stage (mean±SD values for ISS-1, ISS-2 and ISS-3 were: 31±29ng/mL, 47±52ng/mL and 408±695ng/mL, respectively; p = 0.03). Serum Cys-C correlated also with ISS stage (the values for ISS-1, ISS-2 and ISS-3 were: 0.85±0.19mg/L, 0.94±0.24mg/L and 2.15±0.98mg/L, respectively; p = 0.01), while urinary Cys-C correlated with 24-h proteinuria (r = 0.564, p = 0.001).

Conclusions: Our data suggest that almost all newly diagnosed symptomatic MM patients have tubular damage as assessed by elevated urinary NGAL suggesting that renal impairment is present very early in the disease course. Measurement of urinary NGAL and serum Cys-C offers valuable information for the kidney function of MM patients and their measurement may help in the identification of patients with high risk for the development of acute renal failure. The value of KIM-1 seems to be very low in myeloma reflecting the differences in the pathogenesis of myeloma-related renal dysfunction than toxic acute renal injury of other etiologies.

CLINICAL CHEMISTRY, Vol. 60, No. 10, Supplement, 2014
